Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY SCIENCE AND FINANCE.

VOLUME LXVII.

(Second Series.)

FROM APRIL 14, 1911, TO OCTOBER 6, 1911.

ALSO

"THE ELECTRICIAN"
COMMERCIAL AND INDUSTRIAL SUPPLEMENT,

APRIL 14, 1911, TO OCTOBER 6, 1911.

ALL RIGHTS RESERVED.

LONDON:
Published by GEORGE TUCKER, at the Editorial Printing and Publishing Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street.

1911.

INDEX TO "THE ELECTRICIAN."

VOL. LXVII.

(Second Series.)

SPECIAL INDEXES.

	PAGE
... and Industrial Supplement ..	10
... Foreign and General Notes	7
... Meetings, Reports, Dividends, ... Returns, &c.	8
... New Electrical, &c.) Registered	9

Pages in these Indexes are not included in the GENERAL INDEX.

SUB-HEADINGS IN GENERAL INDEX.

	PAGE
Bankruptcies	3
Institution of Electrical Engineers	4
Legal Intelligence	5
Obituary	5
Parliamentary Intelligence ..	5
Personal	6
Reviews	6
Telegraphy	7
Telephony	7
Wireless Telegraphy and Telephony	7
Works, &c., Descriptions of	7

Names of Authors of Articles and Papers are indexed alphabetically in the GENERAL INDEX, *and not under the sub-headings.*

General Alphabetical Index.

Thus figures denote that the subject matter is a "Leading Article" or in the "Editorial Notes." When the sign (C) is placed after a title it signifies that the article in question appeared in the Correspondence columns.

NOTES.

The Competent Person.

[illegible] of a qualifying adjective has often given rise to [illegible] legal documents for the reason that the mean[illegible] word frequently depends upon the connection in [illegible] used. A case in point is the word "competent" [illegible] Home Office rules relating to mines. Recently a [illegible] was inaugurated against some mining officials [illegible] for employing a responsible man who, it was [illegible] not competent. Mr. Robert Nelson, H.M. [illegible] Inspector of Mines, in giving evidence, stated [illegible] found a haulage motor of which the commutator was insufficiently protected, and that the earthing was defective; further, the jointing and supporting of certain cable was not all that was to be desired. On the other hand it was stated in evidence for the defence, that the official in question had had a lengthy experience, first in mechanical work and subsequently in electrical work, and in the result a decision was given in favour of the defendants.

We do not suppose for a moment that there was any question that the defects mentioned by Mr. Nelson really existed. On the other hand, the term "competent" has not been defined, and thus prosecution is difficult. The fact is a man may be perfectly competent to overhaul motors and carry out general electrical work, and yet be incompetent within the meaning of the word really intended by the Home Office rules. "Competent" in this connection really means that the official in charge realises what is dangerous from the electrical point of view, and knows how to render installations safe. Unfortunately, this is rather special knowledge, and is not necessarily acquired by a man who may have excellent experience in general electrical work. In other words, it is not likely that the Home Office rules will be carried out quite satisfactorily until there has been something akin to an educational campaign for the purpose of instructing officials in the electrical conditions found particularly in mines.

Wireless Interferences.

It is an interesting coincidence that the discussion on Mr. J. E. Taylor's Paper on "Wireless Telegraph Working in relation to Interferences and Perturbations" should synchronise with some editorial remarks in the "Electrical World" on the same subject. But whereas our contemporary, in the issue which has come to hand this week, is concerned regarding the meddlesome antennae of amateurs (antennae which are stated to exist by the score round American cities), the interference experienced by the Post Office stations in this country originates, apart from atmospherics, from licensed installations on board ship, and from public stations in this and other countries. The activities of the casual experimenter evidently require some restriction in the States, since they go so far as the sending out of false news, whilst good communication, even over short distances, is reported to be by no means always

Digitized by Google

possible. The ease with which wireless signals can at present be rendered unintelligible must certainly be disconcerting to the British Admiralty, and Sir OLIVER LODGE's doubt as to the efficacy of wireless communication in time of war is a little disturbing.

AT the Institution meeting last week Commander LORING drew attention to the number of unskilled operators who are now in charge of installations on board ship, owing to the recent great demand for operators. The discussion, however, mainly centred around atmospheric interferences, and those due to the Lodge-Muirhead system. The former certainly seem connected with electrical disturbances in the atmosphere, possibly distant thunderstorms; but, on the other hand, it is difficult to explain their diurnal variation. Mr. DUDDELL's suggestion for overcoming present difficulties by increasing the power of transmitters tenfold did not find favour with Sir OLIVER LODGE or Mr. TAYLOR, the former preferring more accurate tuning and directive transmission; whilst Mr. SÖRENSEN advocated the adoption of the Poulsen system, which, he claimed, caused practically no interference. It is to be hoped, however, that as operators become more skilled, and as tuning is improved, many of the difficulties will disappear, to which end the Post Office will have materially contributed by placing their experience at the disposal of the members of the Institution.

A New Cause of Fires.

OUR contemporary, the "Journal of Gas Lighting," had quite a field day in a recent issue; and all because of that horrid electric light, which it finds so dangerous and whose drawbacks it is for ever doing its best to make the public realise. At Middlesbrough, so we are told, something went wrong with an electrically driven fan in a picture palace; the fan thereupon emitted blue sparks and caused a stampede among the audience Two people were killed and several others injured. Now, apart from the fact that even the "Journal of Gas Lighting" can scarcely expect a ventilating fan to be driven by gas, just such a similar panic might have been caused in a variety of other ways; by a taxi-cab back-firing outside, or a gas mantle in the passage beginning to waggle on its crutch, for instance. The next thing that pleased our contemporary was a possible electrical origin of a "disastrous conflagration at the New York State Capitol at Albany, in which damage was incurred estimated at between £1,600,000 and £2,000,000." And we are almost ashamed to mention the suggested cause; it was the "fusing of an electric wire." Really we are surprised at our contemporary; we thought they had more originality. They might at least have produced another electric fan; we are getting so tired of that wire.

WE understand, however, that the fire was not really due to electrical causes at all. Mr. H. B. RENWICK on hearing the report, and knowing from experience how easily such statements obtain currency in this country, communicated by cable with reliable and authoritative sources in America. He was thereupon assured that there was no evidence to the effect that the fire was caused electrically. But after all, why worry about a little thing like evidence? Evidence went out with the Victorian era. The phrase "fusing of an electric wire" rolls trippingly off the tongue, so why not go on using it? Mr. RENWICK informs us that it is thought the fire was due to the dropping of a lighted match by a careless smoker. We should think it very possible, and we recommend this possible cause of fire to the attention of our contemporary. They might use it occasionally, and vary it by the phrase "caused by looking for a gas leak with a lighted candle," which we believe is quite a favourite occupation in some circles of society.

Symbol for Current.—The "Electrical World" states that the United States Committee of the International Electrotechnical Commission has suggested to the National Electric Light Association that the letter "C" be changed to "I" on the Association's badge.

Paris-Vienna Telephone.—It is announced from Vienna that the telephone line connecting Paris and that city will be opened to the public on the 20th of this month. The tariff is to be 6s. 8d. for an ordinary communication and £1 for an urgent communication.

Simply-made Apparatus for Wireless Telegraphy.—In the current number of "Work" appears the first of a series of articles dealing with this subject. The object of the series is to describe the working principles of wireless telegraphy and to give all the necessary particulars for construction of a short-distance station. A perusal of the first article shows that the idea is well carried out, though the usefulness of the series would be greatly increased if reference were made here and there to standard works on the subject. The series is to be concluded in 12 parts.

"Steering Gear Experiments on the Turbine Yacht 'Albion.'"—In a Paper with this title, read before the Institution of Naval Architects by Dr. Hele-Shaw, F.R.S., and Mr. F. L. Martineau, a description was given of a new electro-hydraulic gear. This gear has been tested in connection with a 20 H.P. steam-steering gear, and it has been found possible to change over from one to the other by merely operating a clutch. Comparative results were very much in favour of the new gear, the essential feature of which consists of a new form of multi-radial plunger pump with eccentric adjustment for the variation of stroke and reversal of flow. An electric motor of about 3 H.P. was shown to be powerful enough for operating the gear, and the quickness of the action and ease of handling were much improved with the new apparatus.

Apparatus for Demonstrating the Kelvin Effect.—Two recent Papers in the "Physikalische Zeitschrift" and in the "Archives" of the Swiss Société de Physique contain an account of a very simple optical means of demonstrating the existence of the above effect. The method is due to Prof. W. König, of Giessen. The material is a U-shaped wire, the bend of which dips into a mercury bath. The current passes down one and up the other side of the U, and its magnitude is so adjusted that the wire becomes red hot for a short portion of its length. The two red patches are found to be displaced upwards or downwards with respect to each other, according to the sign of the Kelvin effect in the material of the wire. Owing to the complicated nature of the heat losses from such a wire, Prof. König has not been able to make the method quantitative.

Squirrel-Cage Rotor with Automatically Varying Resistance.—In a patent recently issued in the United States to Mr. Burton McCollum a description is given of a squirrel-cage secondary for an induction motor so built that it possesses high effective resistance at starting and low resistance under running conditions, the change in resistance taking place automatically as the speed increases. The end-rings are constructed of an alloy of steel containing more than 2·5 per cent. of tungsten. The inventor states that this material has a low resistance for low-frequency currents and a high resistance for high-frequency currents by reason of the magnetic hysteresis loss and skin effect.

Crossing the St. Lawrence with High-Tension Lines.—The "Canadian Engineer" describes in a recent issue the high-tension transmission lines of the Canadian Light & Power Co., which are to extend from St. Timothee to Montreal, a distance of about 26 miles. With the exception of certain points where greater height is required, these lines, consisting of bare cables, are carried on steel towers 52 ft. high, spaced at intervals of 500 ft. The crossing of the St. Lawrence River was, by necessity, one of these special points. The river at this point is about 1,100 yds. wide, the depth at the deepest part being about 30 ft., with a current running at from 7 to 9 miles an hour. The crossing was made by means of erecting on each shore of the river two steel towers approximately 150 ft. in height, and building at the centre of the river two concrete piers extending about 15 ft. above water level, surmounted by a steel tower of 150 ft. in height. The span of the cables from the Caughnawaga side to the river piers will be 1,200 ft., and that from the river tower to the Highlands shore approximately 1,800 ft.

Electrification of Hoosac Tunnel.—The electrification of the Hoosac Tunnel, in western Massachusetts, on the Fitchburg Division of the Boston & Maine Railroad, is rapidly approaching completion, and it is expected that an electric service will be run through the tube within a fortnight. The electrified section will extend from Williamstown to a point seven miles east of the tunnel portal, the length of the tunnel proper being about 5 miles. Both tracks will be electrified and the single-phase system will be employed, with overhead distribution. Electrical energy will be generated by a steam turbine-generator plant located at Zylonite. The construction work in the tunnel is handled by two gangs of 75 men each, and strings of electric lamps are employed extensively on the motor cars which serve as construction trains. A small generating plant is installed on each train for supplying the lamps. The train movements are controlled by electric signals and a continuous telephone connection is maintained between the trains and the tunnel dispatcher's office. The overhead trolley wire will be located 15½ ft. above the track and will be supported at points 100 ft. apart.

Reduction of Tin Dross in an Electric Furnace.—In a Paper on this subject read before the American Electrochemical Society by Mr. R. S. Wile, the author stated that electrical energy was resorted to for the smelting of tin dross because the heat could be internally applied to the slag, which was on the bottom of a shaft-type of furnace, thus enabling the dross to be kept on top of the slag instead of being mixed with it, as was done in the old style of furnace. The dross, being on top, came in contact with the slag only at the point of reduction. The metal then filtered through the dross, while any tin oxide that was volatilised condensed in the colder portion of the furnace. The globules of tin produced in smelting passed down through the slag and lost most of their impurities, so very little refining of the resultant product was necessary. In operation the movable top carbon was brought into contact with the lower stationary carbon, and an arc formed. The slag was thus melted, and the carbon was raised until the proper amount of slag was added. The dross, mixed with the proper percentage of carbon, was added, and the tin tapped from the furnace from time to time. The loss of tin had been kept down to ·25 of 1 per cent., and the average below 1 per cent. The amount of tin recovered varied largely on account of the different percentages in the drosses treated. The average was approximately 2,500 lbs. per day. The plant consisted of two furnaces, connected in series, both being 20 in. in diameter and 80 in. high inside, two 50 kw. transformers and the necessary electrical apparatus. In operation they consumed about 44 kw. During the run it was desired to keep the current as constant as possible, the voltage varying. At the start the voltage of each furnace was about 80 volts, but toward the end, as the slag became less refractory, due to the combination of the iron and zinc of the dross and the slag, the voltage of each furnace dropped as low as 45 to 50 volts. This and an analysis of the slag denoted the end of the operation, when the slag must be drawn out and new put in. This was done alternately with each furnace. The furnaces ran continuously until they had to be relined, which was about every three or four months.

Chemically-Active Modification of Nitrogen Produced by the Electric Discharge.—In the Bakerian Lecture on this subject, which was delivered by the Hon. R. J. Strutt, F.R.S., on Thursday last, it was pointed out that the leading facts established were: (1) That pure nitrogen from whatever source, subjected at a low pressure to the jar discharge, underwent some modification which caused it to glow for a short time after it had been sucked away from the discharge. (2) The glow which was emitted while the gas returned to its normal condition was not destroyed by the removal of ions. It was weakened by heating, intensified by cooling. This seemed to favour the view that it was due to the re-combination of dissociated atoms. (3) The modified nitrogen acted on ordinary phosphorus, combining with it, and at the same time forming much red phosphorus. (4) It combined with sodium and also with mercury at a gentle heat (say, 150°C.), forming in the latter case an explosive compound, and in each case developing the line spectrum of the metal concerned. It also developed the line spectra of other metals, probably combining with them. (5) It developed the band spectra of compounds, when these were vaporised in it, giving in many cases spectra of substances too unstable to be examined at the temperature of the Bunsen flame. (6) It attacked acetylene, and substances like ethyl iodide or chloroform, setting the halogen free when there was one, and combining with the carbon to form cyanogen. This was proved by the brilliant cyanogen spectrum produced, and by direct chemical tests, such as the formation of Prussian blue. (7) It attacked nitric oxide, with the formation, strangely enough, of nitrogen peroxide, a more oxidised substance.

The Lighting of a Small Room.—In a Paper read recently before the Chicago Section of the Illuminating Engineering Society, Mr. J. R. Cravath described in detail certain comparative tests of illuminating equipments conducted in a living room 16·5 ft. long, 12 ft. wide and 8·5 ft. high. The colour of the ceiling was very light cream; the walls were covered with light green rough paper. Red portières were placed over the door spaces and green window shades were drawn down over the windows during the tests. In the geometrical centre of the ceiling was placed a single lighting unit, consisting during all tests of a 160-watt tungsten lamp giving 78·9 mean horizontal candle-power, equivalent to 773 lumens. Observations of the illumination obtained over a plane 3·5 ft. above the floor were made with the lamp equipped with various shades and reflectors. The author expressed the opinion that the semi-indirect system with opal reflector was far preferable to the opal ball arrangement, because it was not only more restful to the eyes, but more efficient. He said that the semi-indirect system occupied a place midway between the direct system using opal reflectors and the indirect with opaque reflectors; it was not as comfortable as the indirect, and it caused more pronounced shadow, but it was more efficient and did not hide the source of light entirely where some light was wanted for decorative effects. The author concluded from the tests that the ratio of measured efficiency between a direct system using efficient translucent reflectors and an efficient indirect system in a room of the kind tested was as 3 to 5. What the practical working efficiency or "efficacy" of the two systems was for different purposes depended on the particular conditions and uses of the room. The tests indicated that the measured efficiency of a direct system using enclosing globes was a little higher than an

Digitized by Google

indirect system with opaque reflectors, although lower than a semi-indirect system with translucent reflectors. Tests were also made to determine the effect of shadows thrown by an 8 in. disc placed 15 in. from the test plate between this plate and the light source. The shadow reduced the illumination on the test plate by 86 per cent. when the opal reflector was used at the ceiling; 50 per cent. with the indirect lighting arrangement with mirror reflector, and 61 per cent. with the semi-indirect system with opal reflector pointed upwards. The shadow with the indirect system was less objectionable than with the direct system.

Surface Combustion and its Industrial Applications.—At the Royal Institution on Thursdays, March 30th and April 6th, Prof. W. A. Bone, F.R.S., delivered a lecture on this subject. In the first lecture he dealt with the scientific aspects of surface combustion, a phenomenon which was due to the accelerating influence of hot surfaces at all temperatures upon chemical changes in gaseous systems. Davy, in 1816, had discovered that certain substances when brought into contact with hot platinum burnt without flame, while knowledge of the subject was still further advanced in 1823 by a discovery of Dulong and Thénard, which showed that all hot solids accelerated combustion, though platinum did so in an eminent degree. Further, in contact with platinum, hydrogen was burnt preferentially to hydro-carbons in a defective supply of oxygen, which was the opposite of what was now known to occur in ordinary explosive combustion. Various theories were advanced in the early days by Fusinieri, Döbereiner, de la Rive and Faraday to account for this phenomenon. Döbereiner found that platinum black absorbed oxygen, which could be burnt out by hydrogen. He, therefore, thought that platinum acted only as a carrier, while Fusinieri considered that platinum condensed the hydrogen. Other investigators were found in support of both views; no definite decision was come to, however, between 1836 and a comparatively recent date. The view expressed by Frederick Siemens that surfaces in contact with flame not only hindered combustion, but promoted dissociation, was doubtless largely the cause of this. The lecturer then performed a number of experiments to show the stimulation of the activity of a surface by hydrogen and by carbon monoxide, the formation in certain cases of protective layers of oxygen at the surface which retard combustion, the hindering influence of moisture on the surface combustion of carbon monoxide and the electrical condition of surfaces during combustion. In his second lecture Prof. Bone gave a demonstration of a process of "Incandescent Surface Combustion." For this purpose a bed of refractory granular material was used. This was first heated externally by a flame, but when the bed became fairly warm the flame was withdrawn, and the bed was then brought to incandescence by a blast of fuel and air which was passed into it. In this way very efficient combustion was obtained entirely without flame, but giving radiant heat. This process was shown to be applicable to a number of uses, including diaphragm heating, especially in relation to the concentration of aqueous solutions by radiant heat from an incandescent surface in a plane above the surface of the liquid. It was also shown how the process could be adapted to the heating of muffle and crucible furnaces by surface combustion in a bed of refractory granular material of the kind mentioned above, how copper could be brazed by radiant heat from a similar incandescent bed, and how multitubular boilers could be fired "gaseously" by surface combustion, whereby a high rate of evaporation, 21 lb. per square foot of heating surface, combined with a high thermal efficiency of 94 per cent. on the net calorific value of the gas, might be obtained.

PERSONAL NOTES.

Mr. Charles L. Edgar, president and general manager of the Edison Electric Illuminating Co., of Boston, U.S.A., and party sailed from New York on March 30 for an extended period of rest in Europe. Mr. Edgar brings his car with him. He visits England, France, Italy and Germany. Mrs. Edgar and Mr. Edgar, jun., are of the party.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. G. F. C. Searle continues his article entitled "On Resistances with Current and Potential Terminals."

Mr. J. Härdén contributes an article on "A Curious Coherer Phenomenon."

Electric lighting has been adopted for the extensions of Victoria Barracks, Windsor. A description is given of the installation.

At the meeting of the Institution of Electrical Engineers last week an interesting discussion took place on Mr. J. E. Taylor's Paper entitled "Wireless Telegraph Working in Relation to Interferences and Perturbations."

Mr. W. B. Woodhouse read a Paper last week before the Yorkshire Local Section of the Institution of Electrical Engineers on "Public Electric Supply in Country Districts." This subject is also considered in our Leading Article.

We give an account of the discussion at the meeting of the Birmingham Local Section when Mr. S. P. Smith read his Paper on "The Non-salient Pole Turbo-alternator and its Characteristics."

We give an account of Sir J. J. Thomson's concluding Royal Institution lectures on "Radiant Energy and Matter"; and also of his discourse last Friday evening on a "New Method of Chemical Analysis."

We have received an interesting communication from Mr. J. T. Irwin on the subject of "Electricity Meters."

At a recent meeting of the Physical Society Prof. G. W. O. Howe read a Paper on "Oscillatory Currents in Coupled Circuits."

Announcement is made of the registration of a combination of the well-known engineering firms of Stothert & Pitt (Ltd.) and Wellman, Seaver & Head (Ltd.), under the style of "Wellman, Head, Stothert & Pitt (Ltd.)."

In a report to the Tramways Committee at Bradford, Mr. C. J. Spencer made some interesting observations as to the discrimination between, and rewarding of, tramway employés.

Leeds City Council have decided to make reductions in the charges for electricity for power and heating.

Parliamentary.—Select Committees of the House of Commons have approved the preambles of the Northampton Corporation, the Liverpool Overhead Railway and the Nottinghamshire and Derbyshire Tramways Bills.

Legal.—On Saturday Mr. Justice Joyce delivered judgment in the action brought by the London Electric Supply Corpn. to restrain the Westminster Electric Supply Corpn. from inducing plaintiffs' consumers in the Westminster area to take electric current from the defendant company. After reviewing the facts, his lordship dismissed the action, with costs.

An interesting point came before the Judge at Hastings County Court, raising the question of what constitutes "passengers' luggage" on a tramcar.

Companies' Meetings and Reports.—At the meeting of the Metropolitan Electric Tramways last week the chairman, Mr. E. Garcke, gave an interesting account of the progress of the company, and also of the development of the undertaking of the North Metropolitan Electric Power Supply Co., in which the Company is interested.

In another portion of the Paper will be found a number of interesting reports of the meetings and abstracts of the directors' reports of provincial electric supply and tramway companies.

OBITUARY.

WILLIAM MIDDLETON.—We regret to record the death of Mr. Wm. Middleton, A.M.I.E.E., assistant works superintendent to the Newcastle & District Electric Lighting Co. Mr. Middleton was examining the back of a switchboard at the Close power station on Thursday afternoon last when a short-circuit occurred. His face and hands were badly burned and the upper part of his clothing caught fire. A doctor was immediately sent for and the injured man was conveyed to the Gresham private hospital, where he succumbed to his injuries on Friday morning. At the coroner's inquest the jury returned a verdict of "Death from shock following electric burns accidentally sustained." The jury expressed the opinion that a partition between the positive and negative bars should be provided in future to prevent danger from any accident or short-circuit. Mr. Middleton was only 37 years of age at his death and had been in the service of the above Company for 14 years. He served his apprenticeship with Messrs. C. A. Parsons & Co., and when quite a young man occupied responsible positions. He was married in 1899 and leaves a widow and four young children.

APPOINTMENTS VACANT AND FILLED.

One or two draughtsmen are wanted by a large electrical firm. See an advertisement.

The Electrical Power Storage Co., 4, Great Winchester-street, London, E.C., require a qualified sales manager. Applicants must have had experience of storage batteries, and possess a good connection. See an advertisement.

An electrician is required to take charge of an electric lighting installation and control of three assistants at a North of England cement factory. See an advertisement.

The Yorkshire Electric Power Co. have vacancies for a sales engineer (salary £200 per annum), and for an assistant construction engineer (salary £156). Further particulars are given in an advertisement. Applications to Mr. W. B. Woodhouse, chief engineer of the company, Thornhill, Dewsbury.

London County Council require two charge shift engineers for the Greenwich generating station. Salary (in each case) £250, rising to £300. Council offices, Spring-gardens, S.W., to whom applications by 11 a.m. April 20.

Mr. F. H. Peat took up his position as general manager of the South Eastern & Chatham Railways on April 1.

Mr. J. E. Links (traffic superintendent of Bendigo (Victoria) tramways) has been appointed to a similar position in the Launceston (Tasmania) municipal tramways department.

INSTITUTIONS AND SOCIETIES.

Institution of Civil Engineers.—The monthly ballot at this Institution on March resulted in the election of three honorary members, viz., Lord Brassey, G.C.B., Alfred Noble, and the Duke of Northumberland, K.G., P.C.

British Science Guild.—The fifth annual meeting of this association took place at the Mansion House on Friday last, the Lord Mayor (Sir Vesey Strong) being in the chair. Sir Wm. White, in submitting the report, drew attention to a statement which had been prepared by Prof. R. A. Gregory, giving a full statement of endowments for higher education and research announced during the past year. Considering first the gifts for purposes of research, it appeared that these amounted they amounted to about £70,000 (omitting Mr. Otto Beit's munificent gift in 1909 of £215,000 for medical research in London). A comparison of this amount with the funds available for the same purposes in Germany and the United States was instructive. In the United States the gifts to research amounted to nearly one million pounds; and the actual grants for research made by the Carnegie Institution alone amounted to £90,000, or £20,000 more than the addition to our endowments. A single donor gave £284,000 for the advancement of science in France; £100,000 sterling had been subscribed in Germany for the Kaiser Wilhelm Society for the Promotion of Scientific Research. As regards educational endowments, gifts amounting to about one and a quarter million pounds were made for buildings and equipment in connection with higher education in England. The gifts for similar purposes in the United States during the same period amounted to £4,000,000 sterling. Prussia added a new technical university to the seven previously established in Germany, and the ordinary endowments of the other universities had increased by an amount of £500,000 in excess of what it was five years ago. The report also called attention to the need of better organisation in those Government departments dealing with education. At present the primary, secondary and technical education of the country was controlled by the Board of Education, while the Treasury was supreme in matters connected with the Universities. One way out of the difficulties would be to transfer certain services to the Board of Education and to appoint an advisory committee to deal with higher education. Another way would be to appoint a Minister of Education. The Technical Education Committee had drawn up a report dwelling upon the need of co-operation and co-ordination in higher education. At present a great deal of money was wasted owing to overlapping and clashing of interests. The report was not adopted, the president, Lord Haldane, delivered an address in which he dealt with technical education. He took up the view that things were not so bad as were made out and altogether questioned the opinions expressed in the report.

Tramways and Light Railways Association.—The "Journal" of the association for April contains a report on "Speed Indicators," issued at the suggestion of the Board of Trade. The members of the Committee signing the report are the following: Messrs. [illegible], chief engineer, Metropolitan Electric Tramways (chairman); R. W. Cramp, general manager, Birmingham and Midland Tramways Joint Committee; H. England, general manager, Wakefield & District Light Railways Co.; W. E. Ireland, rolling stock superintendent, L.C.C. Tramways; C. W. Mallins, general manager, Liverpool Corporation Tramways; and S. Sellon. The "Journal" is a "special" number, copies of which can be obtained by non-members at 2s. 6d. each. The report is fully illustrated, and covers 43 pages. The announcement is made that the annual congress of the Association will be held at Edinburgh on July 13th and 14th next.

Rontgen Society.—The problem of secondary X-radiation—the radiation emitted from a metal or other substance when placed in the path of the primary beam from an X-ray tube—formed the subject of an address by Prof. C. G. Barkla, of King's College, London, at the meeting of the Röntgen Society on April 6th. The value therapeutically of the rays obtained in this manner is that they are very soft, or readily absorbable, whereas in the case of the direct sheaf of rays from the tube these ultra-soft rays have no influence, being filtered away before reaching the exterior of the glass. Prof. Barkla divided this secondary radiation into three species: radiation which was entirely scattered; secondary fluorescent radiation, which was by far the most valuable; and corpuscular radiation. The first of these emissions was that which proceeded from air or from gases containing elements of the lighter atomic weights—carbonic acid gas, for example—and was simply scattered in every direction. The second type was that which proceeded from heavier gases, such as those containing bromine or iodine, or metals, such as copper, zinc, lead and iron, when placed in the path of the primary beam. A distinction must be made, Prof. Barkla remarked, between the effect of filtration and that of secondary radiation. With radiation going through filters of metal the primary rays as well as the secondary rays had a place in the residue. In order to get pure secondary radiation one must have the surface of incidence—i.e., the metal plate—at a certain angle so that, to speak in terms of light, the radiation was reflected from it. The difference between the primary and the secondary radiation lay in the almost complete homogeneity of the latter. The essential condition for its production—a law which was also true of the fluorescence of ordinary light—was that the primary beam should be of a more penetrating type than the secondary radiation characteristic of the particular element—lead, for example—employed. Every element had its own characteristic radiation, and it was possible even to plot out a kind of spectrum, using degrees of absorbability instead of wave-lengths. The thickness of aluminium necessary to absorb half the secondary radiation varied from 1/350 cm. in the case of iron to 1/22 cm. in the case of cerium. The thickness of water absorbing half the radiation was 1/25 cm. in the case of iron and varied more or less according to the atomic weight of the metal until, in the case of silver, 3 cm. were required before the radiation would fall to half value, and 6 cm. in the case of cerium. In therapeutics the particular metal would be chosen according to the thickness of the part of the tissues to be penetrated. The X-rays being electro-magnetic in nature, it followed that there was a third type of secondary radiation, to which he might be given the name of corpuscular. It corresponded to the β radiation of radium but was much less available for practical use. All heavy substances exposed to the primary beam emitted this particular radiation, but the rays passed to only an infinitesimal distance.

Liverpool British Insulated Engineering Society.—This Society held their usual fortnightly meeting in the George Holt Physics Theatre, Liverpool University, on March 29, Mr. W. Aitken, M.I.E.E., being in the chair. Dr. Gwilym Owen gave a most interesting lecture on "Electrons and Röntgen Rays." The lecture was fully illustrated by experiments, Dr. Owen being assisted in these by the University demonstrators, Messrs. Pye and Welch. The thanks of the meeting were conveyed to the University authorities and Dr. Owen for their kindness in allowing the B.I. Engineering Society to meet there that evening, and for the interest taken in the work and aims of the Society generally.

Metropolitan Electric Supply Co.—The annual staff dinner of the Company was held on Friday last when there was a numerous gathering of staff and guests, and a very enjoyable evening was spent under the chairmanship of Mr. J. S. Highfield. The proceedings gained through not being too formal, and there was plenty of humour in the speeches of Mr. Cunliffe Owen who proposed "Our Guests," Mr. A. Diósy who responded, Mr. Robert Hammond who proposed "The Company," the reply being in the hands of Mr. Frank Bailey, and Sir Robert Cranston, K.C.V.O., who proposed "The Chairman." Mr. F. Hipwell, who was mainly responsible for organising the dinner, gave a humorous description of the worried looks of members of the staff as portrayed by dinner photographs; but judging by the prosperous condition of the Company there does not seem to be much cause for complaint. An excellent musical programme was intermingled with the speeches.

THE ELECTRICAL PRODUCTION OF STEEL AT THE WORKS OF THE EICHER-HÜTTENVEREINS LE GALLAIS METZ & CO. AT DOMMELDINGEN.*

On account of their favourable position in the valley of the Grand Duchy of Luxemburg, Dommeldingen and its vicinity are specially suitable places for the erection of large iron works, the more so as the native ore, which contains from 40 to 45 per cent. of iron, can be used without any great transport expenses being necessary.

The Eicher-Hüttenverein have three ordinary furnaces in use at Dommeldingen at the present time, which are each capable of producing about 100 tons of pig-iron per day. The furnace gas is supplied to gas engines, which in turn provide electrical energy for the furnaces.

Generating and Transforming Plant.

The transformer equipment, which is used in connection with the two 4-ton single-phase furnaces, described below, is usually supplied with energy from a gas-driven generator, delivering three-phase current at a pressure of 5,000 volts and a frequency of 25, when running at 94 revs. per min. Energy from the same set is also supplied to the town of Luxemburg, so that in the operation of the new installation care has to be taken not too greatly to reduce the power factor. For this reason an over-excited synchronous motor is used in the converter set. The high-tension current from the power house is stepped down to a pressure of 500 volts by a 600 kw. static transformer, whence it is supplied through suitable switchgear to the two converter sets.

Each convertor set consists of an asynchronous three-phase starting motor designed for intermittent working, and having a capacity of 140 H.P. when supplied with current at 500 volts and a frequency of 50; a single-phase generator with a capacity of 825 to 950 k.v.a., with pressure varying from 3,000 to 3,500 volts; a 715 H.P. synchronous three-phase motor with a power factor of unity and supplied with current at 5,000 volts and a frequency of 50; and an exciting set. The whole of these machines are fixed on a common bedplate

A special coupling, which is worked by a hand lever, allows the starting motor to be cut off from the set during the working period, while, should its speed exceed during starting the synchronous speed of the synchronous motor, a centrifugal arrangement fixed at the end of the shaft, cuts it out of circuit, so that the machine cannot be strained by the high speed. After synchronism has been obtained between the asynchronous motor and the generator at the central station, the starting motor is cut out by means of the coupling. On account of the load being thus taken off the speed of this motor rises to a certain value, when the centrifugal arrangement, mentioned above, short-circuits two of its phases. The decrease in voltage which occurs on this account causes an automatic cut-out behind the switchboard to come into action. This in turn operates a three-pole switch, and cuts out the motor from the network. This switch is fitted with coils which during the usual course of working act as hold-off magnets, and keep the switch closed. The short-circuiting arrangement consists of simple contacts against which brushes of thin copper strip are pressed by means of a knee-jointed lever. When a pressure of 500 volts is reached a resistance is placed in series with each of the magnets, and when the voltage has risen about another 20 per cent. the switch operates. This arrangement is necessary, as cutting of the voltage off only one phase would not be sufficient. To guard against arcing at these switches the upper contact is provided with a spark arrester, the circuit on which is closed before the main brushes come into action, while it opens after them. Switching in is effected by means of a rod switch from the front of the switchboard.

The switchgear, which is arranged in the basement of the transformer house, includes, besides that dealing with the cables going out to the furnaces, the generator oil switches. These are fitted with maximum cut-outs, and their position is made known by means of control lamps on the switchboard. Further, there are the usual current and pressure transformers for the measuring instruments, as well as selector switches on the high pressure bus bars. In connection with the oil switches used, it may be mentioned that these are fitted with automatic overload cut-outs. The switch is automatically returned to its off position by means of spring power, the spring being released by an electromagnet. The winding of this magnet is placed directly in series with the high pressure system. The contact arrangement by means of which the signal lamps are switched on and off is arranged at the back of the switchboard. The switchboard consists of five panels, two of which are provided with instruments in connection with the synchronous motor. On the third is mounted an aperiodic ammeter which is placed in the three-phase furnace circuit, an aperiodic voltmeter for the 500-volt three-phase network, an aperiodic voltmeter for the exciter circuit, and a voltmeter change-over switch, as well as phase and frequency measurers. The arrangements of the latter are shown in Fig. 1.

Furnace Installation.

The steel furnace building is of girder construction filled in with bricks, and is divided into two shops each 60 ft. wide by 450 ft. long. The southern shop contains the two single-phase furnaces, three-phase furnace No. II, and the space for a fourth furnace. The general arrangement is shown in Fig. 2. In this space at the present time a ¾-ton test furnace is installed. There is also a Wellmann mixer, fitted with tipping gear, of from 15 to 20 tons capacity, a drying oven for cores and moulds, the core factory and foundry, as well as an automatically working apparatus for mixing the foundry sand. In front of each furnace, which is raised 10 ft. from the floor, and on the tipping side, are tracks for the trucks carrying the molten metal, and immediately behind them a pit into which the slag can be poured.

Adjacent to this shop is another in which are placed various machines for working the castings. The largest and most complicated pieces can be cleaned here, and leave the works quite ready for use. The machines themselves are practically exclusively driven by motors, the larger ones being worked on the individual drive system.

The incoming cables from the convertor house are run in ducts direct to the south wall of the furnace house, whence each goes singly to the place where it is employed. In order to allow plenty of room comfortably to work on the furnaces the latter are placed some distance apart, as shown in Fig. 2. The furnace platform is built out from the south wall of the furnace room on reinforced concrete platforms. On the outer side it is provided with iron railings, and is supported by eight square pillars. The furnace platfrom is reached from the floor by means of concrete steps.

The most important part of an induction furnace is the transformer, which, as is well known, works on the following principle: The single-phase current flowing through the primary winding induces a large current in the melting rings which, to a certain extent, forms a short-circuited secondary winding. This secondary current brings the whole content to a molten condition. Alterations in the current strength, or the temperature, can be easily effected by varying the machine voltage by means of the exciter regulator. In the case of three-phase furnaces voltage regulation may be effected by means of a regulating transformer and rheostat.

The two single-phase furnaces at Dommeldingen are of the same type and construction. Each furnace contains a furnace transformer with a maximum output of 950 k.v.a., the pressure being 3,500 volts and the frequency 25. The iron core, which is built up of transformer sheet iron and is insulated with paper, carries on each limb a well-insulated primary winding. This surrounds the secondary winding, whose ends are fastened to the cast-steel pole plates. Round the transformer windings on each leg are placed protective coverings, which rest on projections from the lower yoke. This covering is surrounded at a short distance by a second covering, whose lower flange rests on the brickwork of the wall foundations. This second covering affords a special protection to the winding against heat radiating from the brick work, while the inner covering acts principally as a cooling cover, and by it cold air is brought in. As the covering cannot, of course, be closed, the separating pieces are bridged over with micanite. By means of a ventilator cold air is drawn through the space between the winding and the inner covering and between the air ducts on the transformer core, so that the temperature of the winding is kept within certain limits. By this arrangement of the protective covering combined with the great cooling effect obtained by the blast, the temperature of the windings never exceeds that laid down in the V.D.E. rules, in spite of the fact that a furnace working at a temperature of from 1,600°C. to 1,700°C. is within a foot. As the furnace is arranged for tipping, the tube through which the blast is brought in must be provided with a telescopic arrangement and draw-out pieces fitting into the main pipe through which both transformers arms are fed. Care is taken to provide a similar division and distribution of the air inside the cooling cover. By a special arrangement of the parts, which prevents the escape of the air, the windings are cut off from the atmosphere, and the falling in of foreign bodies and dust is thus prevented, while owing to the care taken, any contact with the current-carrying part is rendered impossible. The primary winding on both legs is held fast to the foundations by means of process screws and plates, and rests on coil carriers. The connections come in through the lower air duct being insulated at this point by stabilit brushes. Connection to the secondary winding are made from above, and are fixed to the pole plate ends which project from the furnace cover. It is especially important so to arrange the windings that any deformation and short-circuits, which might thus occur, are prevented. The primary coils are connected together by means of copper strips placed under the furnace. On each side of the furnace is placed a semi-circula

* Abstract of an article in the "Electrotechnische Zeitschrift."

Digitized by Google

brass bar, which is connected to one pole of the winding, and which is used for conveying the current from the brush carriers. On this bar slide three carbon brushes, whose holders are fixed to a gas pipe by means of screwed plugs, insulated with stabilit bushes. The feeder cable is led through this pipe to the brushes.

In order to be able to measure the blast temperature at different places in the transformer winding three thermo-elements of copper-constantan are arranged in each of the cooling covers. Conductors from these are led to a multi-way switch on the wall of the switchboard, and are there connected to a galvanometer. The galvanometer is calibrated both in milli-volts and degrees.

A 75 H.P. three-phase motor connected to the 500-volt network, and running at 975 revs. per min. is placed at an angle of 75 deg. to the horizontal and drives a centrifugal ventilator. The capacity of this latter is 26,000 cubic ft. per min., the air being drawn through a filter house placed outside the south wall. Filter cloths catch any dust, so that the air, when it finally reaches the pipes, is practically clean. The regulation of the air supplied is effected by altering the speed of the ventilator motor. Behind the ventilator and immediately in front of the first furnace dampers are fixed to regulate the supply of air to each single furnace. A second ventilator of the same size as the first serves as a reserve. The ventilator is housed in with sheet iron, while the motor is so arranged that the flywheel can quickly and simply be removed.

Tipping is mechanically effected by means of a 10 H.P. three-phase crane motor working off the 500-volt circuit, and running at a speed of 710 revs. per min. It is switched in or out from a motor switchboard fixed to the wall. It is controlled from the platform by means of a controller placed near the instrument switchboard for the fur-

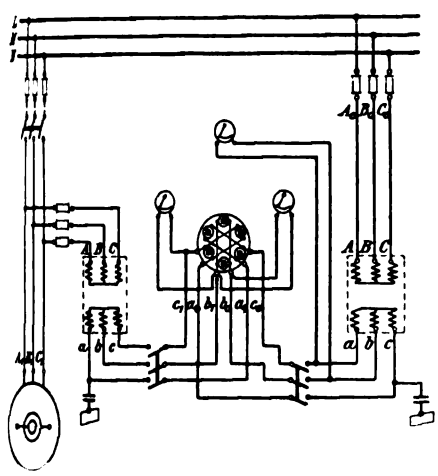

FIG. 1.—DIAGRAM OF PHASE AND FREQUENCY METERS.

nace. Great emphasis has been laid on the exact operation of the tipping equipment, seeing what would be the direful consequences of any breakdown. A differential hand brake worked by a magnet automatically provides a practically instantaneous stoppage of the tipping equipment directly the motor is cut out, and this fine subdivision of the control allows very small tipping movements to be made. The method of operation of the brake magnet, which is in parallel with the motor, is such that on starting the motor the brake magnet is switched in and the brake lifted. When the motor is cut out the counterpoise falls and the brake comes into action. The brake magnet consists of a three-limbed solenoid. The brake weight is both raised and let drop softly and without jerks by means of an air damping arrangement, its very simple construction allowing it to be easily protected against dirt and rough handling. At the moment of switching on a certain wattless current flows through it. As the pull of the magnet falls with the decreasing voltage, the leads have to be so arranged that there is no great voltage drop. When the crane is drawn up the current is greatly choked so that the energy consumed is very small, even when the coil is left on for some time. It is easy to avoid the winding burning out, owing to the brake rod of the magnet being overloaded, fuses are provided.

The maximum tipping angle of the furnace is 45 deg. for pouring steel and 17 deg. in a backward direction for pouring slag. In order that these limits may not be exceeded, overrunning switches which break the circuit are provided. These are fitted with automatic working in gear.

The furnaces are built after the general form of the Martin furnace. The mechanical part includes a roller-way carrying the furnace, and the furnace proper with the two doors for charging, pouring, removing the slag and puddling. The tipping arrangement consists mechanically of two upper and two lower cast-steel runways, on which there are two sets of rollers, each consisting of 11 cast-iron rollers 160 mm. in diameter. A geared wheel is fixed rigidly to these rollers and engages with two steel driving wheels fixed on a shaft which is driven through a leather coupling by means of the motor mentioned above.

The furnace body proper consists of iron plates ¾ in. thick, which are surrounded by the transformer core and are coated on the inner side with fire-resisting brickwork.

In Dommeldingen, owing to the continuous working, basic coating material was used. The heating of furnace rings requires, when working in the ordinary way, a load of about 180 kw. on the 350 kw. furnace for about 8 hours. The furnace is then fed with molten pig-iron, so that the energy taken becomes nearly the standard value, and can be brought by regulating the machine voltage to any desired amount, according to the requirements of the charge. On the puddling side of the furnace platform are provided two doors which can be drawn up by means of a winch and the space in front of the pouring snout left free for tipping. The molten metal is poured into a large cauldron of 20 tons capacity, which is brought up by a travelling crane. In order easily to get rid of the slag, gullies are arranged in front of the furnace leading below, whence the slag is taken away in special barrows.

The position of the furnaces and the switchboards is shown in Fig. 2. One of these panels is used for controlling the single-phase furnaces and the other for controlling the three-phase furnace and the ¾-ton experimental furnace. A switch pillar has been erected for each furnace. The pillars for the single-phase furnaces are each fitted with a power indicator, an ammeter and a voltmeter (which are connected to current and pressure transformers in the cells under the furnace floor), and a hand lever for working the oil switch, as well as two coupled hand-wheels for the remote control of the main exciter regulators. Near the switch pillar is the controller for the tipping motor and a loud speaking telephone mounted on a pillar. On the wall are fixed the ammeter and voltmeters for the tipping motor, as well as the motor switchboard

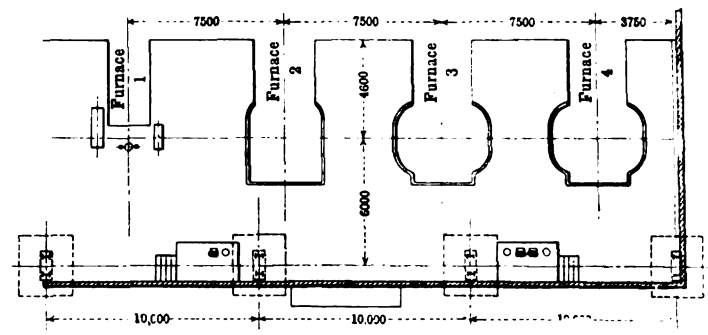

FIG. 2.—GENERAL ARRANGEMENTS OF THE FURNACES AT DOMMELDINGEN.

and the temperature galvanometer with its three-way switch which was mentioned above. The wooden floor of the platform is insulated with rubber matting.

Underneath the furnace floor is a room in which are fixed the switch cells for the furnace and the regulators. Here also are the ventilators mounted on concrete foundations, as well as the pipes in connection therewith. The regulating transformer for the three-phase furnace is also fixed here. The switch cells for the single-phase furnaces are each 3 ft. 6 in. wide, and are separated from each other by a concrete wall 6 in. thick. The two-core cable from the power house ends in a sealing off box, whence each cable passes through the cell and is fitted with a single-pole separating switch, current transformer, voltage transformer whose fuses are in parallel with the main circuit, and a double-pole oil switch remotely controlled from the switchboard. All the high-tension gear is contained in this room, and the instruments on the switch pillars carry only low-pressure currents. The walls of the switch-room are plastered and the room is kept free from dust by the doors. From the cells the cables go in a trench to the brush holders on the furnaces. The bars on the furnaces are of semicircular shape to allow the current to be kept on during tipping.

The general arrangement of the three-phase furnace is similar to that of the single-phase furnace. The furnace is of circular shape. Naturally three-wound cores are used and three induction rings. The yoke is of horseshoe shape, so that it encloses the working space on three sides. The three-phase furnace has the important advantage over the single-phase type that, owing to the arrangement of the cores in the molten bath, a regular revolving field is set up, which causes the molten material to be kept in motion, thus leading to a good mixture of the contents. Fresh portions of the charge are

Digitized by Google

always, therefore, coming in contact with the slag, so that the refining process is much accelerated. A melting of the scrap also takes place, thanks to the good mixing together of the bath content in a short time, as continually fresh fluid masses are flowing over the scrap pieces and bringing them to the melting point. Combined direct and induction heating is employed in this case also by means of pole plates. The transformer cores are wound with the primary and secondary windings. One end of the latter is connected to a neutral point and the free ends are fixed to wide copper bars which are connected to the pole plates. These are fixed in the furnace foundations at the places where the two melting rings cross the working hearth—that is, at the crossing point of the secondary circuits in that part of the middle hearth which acts as a heating resistance. The charging and tipping of the slag is effected through the two doors at the back. Slag producing ingredients can be introduced through either door. Mechanical tipping of the furnace is effected in the same way as in the case of the single-phase furnace.

The transformer which supplies the three-phase furnace has a maximum output of 400 k.v.a. with a power factor of 0·7. The working voltage is 500 volts and the frequency 50.

In this case, too, the windings are surrounded with induction free covering, through which air from the ventilators is supplied. The furnace voltage is regulated very easily by a transformer, which is connected to the primary 500-volt circuit and to a three-pole rheostat, which allows six different voltages to be used at the furnace. This transformer is air-cooled through an offshoot from the main pipe. In general, the tipping and switching arrangement are similar to those used on the single-phase furnaces.

For communication between central station, transformer house and furnaces a loud-speaking telephone installation is in use. In the furnace house, as mentioned above, a telephone is placed on a pillar near the switchboard, while at the central station and convertor house wall instruments are used. The two furnace positions and the central station can all ring up the transformer station, and can be rung up from thence by using a line-selector drop-annunciator instrument. No arrangement is made for the furnace house to speak to the central station, as this is not necessary.

OSCILLATORY CURRENTS IN COUPLED CIRCUITS.*

BY G. W. O. HOWE, M.SC.

Summary.—The author describes the method of demonstrating with an oscillograph the currents in coupled oscillatory circuits containing capacity and inductance. The oscillation of energy between the circuits is discussed mathematically and the conditions are shown to agree with experimental results. The quenching of the spark in the primary circuit is finally considered.

If a condenser with a capacity of K farads be charged and then discharged through an inductance of L henries, the resultant current is oscillatory if the resistance of the circuit is less than $2\sqrt{L/K}$. The oscillatory current has a logarithmetic decrement of $R/2\sim L$ per period, and if R is small compared with L, a frequency of $\frac{1}{2\pi\sqrt{KL}}$.

By taking condensers and inductances of suitable values, these oscillatory currents can be shown on the lecture screen by means of the Duddell projection oscillograph. To do this conveniently, the ordinary charge and discharge key is replaced by three brushes rubbing on a special commutator which is fixed to the spindle of oscillograph motor, so that a number of similar wave-trains are superimposed on the screen. As shown in Fig. 1, the commutator consists of a brass cylinder, B, certain parts of which are cut away and replaced by insulating material, I. During a short interval the condenser is connected across a direct-current supply, from which it is then disconnected and discharged through an inductance, in series with which is placed the strip OS of the oscillograph, suitably shunted. This oscillatory circuit is only broken while the condenser is being charged. In the experiments shown, the capacity consists of four Western Electric Co. condensers, nominally of 5 mfds., connected in parallel, while the inductance is an air-core choking coil of 28 millihenries with a resistance of 0·32 ohm. The oscillations have a frequency of 220 per second. The curves accompanying this Paper were obtained by placing a photographic film on the tracing desk of the oscillograph and exposing for a few seconds. The measured resistance of the circuit was in all cases about half an ohm, while the resistance calculated from the decrement is about 1·5 ohms. The condensers are, therefore, the main cause of damping in the circuits. By placing a variable resistance in the circuit the damping can be increased until the circuit is made non-oscillatory. When a circuit contains a spark-gap the conditions are somewhat modified, as the resistance in the gap, and therefore the decrement of the circuit, increases as the current decreases in amplitude.

We shall consider the case in which the two oscillatory circuits are adjusted to have the same natural frequency. The second strip of the double oscillograph is put in the new oscillatory circuit, and the two inductances so placed that they mutually affect each other (*see* Fig. 1). When a discharge passes through the primary circuit, energy will be transferred from the primary to the secondary circuit. If the mutual inductance between the coils is low, the rate of this transfer of energy will be small compared with the rate at which energy is fritted away by the damping in the primary circuit. The secondary current will then never be strong enough to have any marked effect on the primary circuit beyond a slight increase in its damping. In the secondary circuit we shall have a train of the natural frequency, increasing in amplitude up to a certain point and then gradually decreasing.

If now the coupling between the two circuits be tightened—*i.e.*, if their mutual inductance be increased—the transfer of energy takes place at a greater rate and goes on until the energy is entirely transferred to the secondary circuit, the amplitude of the primary current being reduced to zero. The action then reverses, the role of primary and secondary being interchanged until the energy has been entirely dissipated.

It can be shown mathematically that, although the two circuits may be tuned to have exactly the same periodic time, T, when oscillating alone, the oscillatory current in each circuit will now be the resultant of two superimposed harmonic oscillations of different frequencies. If T_1 and T_2 be their periodic times, $T_1=\sqrt{T^2+\tau^2}$ and $T_2=\sqrt{T^2-\tau^2}$, where $\tau^2=4\pi^2M\sqrt{K_1K_2}$. We have already seen that $T^2=4\pi^2K_1L_1=4\pi^2K_2L_2$. The ratio $M/\sqrt{L_1L_2}$ is generally known as the coupling and designated by k, so that $\tau^2=kT^2$ and $T_1=T\sqrt{1+k}$ and $T_2=T\sqrt{1-k}$.

The superposition of these two harmonic oscillations of different frequencies will result in beats, and if T_B be the periodic time of

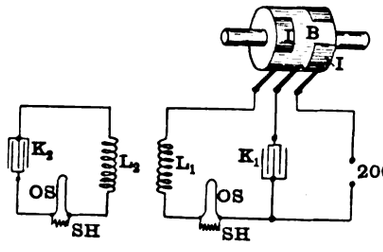

FIG. 1.

these beats, it is evident that $T_B=T_1T_2/(T_1-T_2)$, and that the number of waves in each beat is

$$\frac{T_B}{T}=\frac{\sqrt{1+k}\cdot\sqrt{1-k}}{\sqrt{1+k}-\sqrt{1-k}}$$

A half of this number will be the number of oscillations made by the primary current before the energy has been all transferred to the secondary circuit, which is very important from the point of view of the probability of the spark in a radio-telegraphic sending apparatus being quenched at this moment. In the table the complete oscillations per half-beat is given for various values of the coupling. It will be seen that when the coupling is less than a third, which is always the case in practice, the number of complete oscillations per beat is the reciprocal of the coupling. This agrees very well with the experimental results given in the Paper.

k.	No. of waves per half-beat.	k.	No. of waves per half-beat.
0·05	0·10	0·4	1·1
0·1	0·5	0·5	0·84
0·2	2·4	0·6	0·63
0·3	1·6		

If the coupling is tight it seems to be immaterial whether the damping resistance is placed in the primary or in the secondary circuit. When the coupling is loose it still seems immaterial so far as the secondary circuit is concerned, but not entirely so in respect of the primary circuit. If the frequency of the oscillations is increased beyond a certain point, the Duddell oscillograph will be unable to follow the rapid variations of the current. The only form of oscillograph which can then be used is that depending on the deflection of the cathode rays in a vacuum tube. In radio-telegraphy the high-frequency oscillations are always investigated indirectly by means of a so-called wave meter, which is simply an oscillatory circuit, the natural frequency of which can be varied over a wide range. It will act as a harmonic analyser, picking out and responding to any oscillations of its own frequency in the circuit with which it is loosely coupled.

* Abstract of a Paper read before the Physical Society.

Digitized by Google

In the sending apparatus of a radio-telegraph station we are met with this difficulty. If the primary oscillating circuit containing the spark-gap be loosely coupled with the aerial, the electromagnetic waves sent out will have one definite frequency, but the transfer of energy to the aerial will take place so slowly that the major portion of the primary energy will be frittered away in the spark-gap. If, on the other hand, the circuits be coupled tightly, the energy will surge backwards and forwards between the two circuits and powerful electromagnetic beats will be sent through the ether. This will reduce both the efficiency and the possibility of sharp tuning. The obvious way out of the difficulty is to break the primary oscillating circuit at the first moment that all the energy is transferred to the

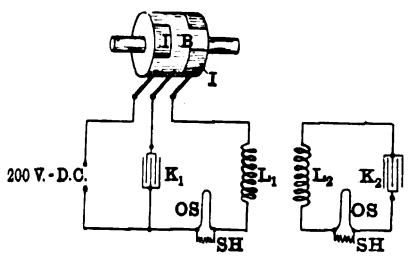

FIG. 2.

aerial, and thus make its return to the primary circuit impossible. Marconi, in 1906, found that by making the spark-gap very short and thus ensuring that no part of the spark-path was very far removed from a large mass of cold metal, the disruptive strength of the gap is so quickly restored that the circuit is effectually broken if the current in it fall to a small value for a short time. The more efficient the quenching of the spark, the shorter will be the time during which the amplitude of the current must remain small in order to prevent the spark restriking, and therefore the tighter can be the coupling. This is of great advantage, as it lessens the time during which energy is being dissipated in the spark.

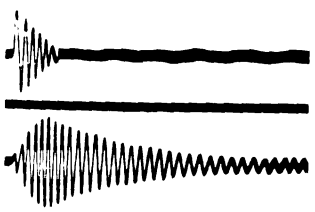

FIG. 3.

To represent this on the oscillograph it is only necessary to break the primary oscillating circuit at the moment when the amplitude of the primary current has fallen to zero. The simplest way of doing this is to rearrange the connections to the commutator as shown in Fig. 2. The speed of the motor must then be adjusted so that the short interval during which the primary current is closed is equal to the time taken for the transfer of energy from the primary to the secondary circuit. The result obtained is shown in Fig. 3. If the quenching of the spark is not effective enough to quench it at the first opportunity it may succeed in so doing the next time the primary amplitude falls to zero. In Fig. 4 the quenching occurs at the third

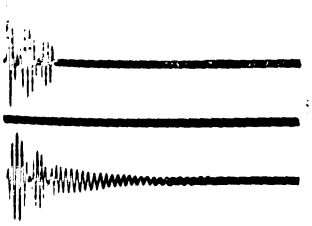

FIG. 4.

current. As a matter of fact a spark-gap would cause the decrement to be much greater than that shown in Fig. 4. The spark may be looked upon as a minimum current cut-out which we try to make as quick-acting as possible.

Attention should perhaps be drawn to the ironless choking coils used in the oscillatory circuits. They were designed by Prof. Mather for general laboratory use. They are wound with six-cored cables, the cores being brought out to a plug-board. The frame work is of wood and fibre and entirely free from metal. The range of inductance is from 7 to 250 millihenries. The power-factor at 50 cycles per second is only 0·03.

ELECTRICITY METERS.

In connection with the recent discussion on Messrs. Ratcliff and Moore's Paper we received the following communication from Mr. J. T. Irwin, which was unfortunately crowded out of our last issue :—

In the Paper presented to the Institution of Electrical Engineers on March 23rd the authors bring out many points which are well worth careful consideration, especially as their conclusions are supported by carefully carried out experiments.

In considering the effect of a rapidly varying load on shunted ampere-hour mercury type meters it is necessary to divide the meters into two classes; first, those like the Ferranti (old) type where the torque is proportional to the square of the current, and, second, those where the torque is proportional to the current.

In the first case, if the ratio L R in the shunt is equal to L R in the bath circuit the currents will divide up proportionally to their resistances and the torque will be proportional to the square of the current in the mains. If the fluctuations of the current are rapid, as for a motor driving a punching machine, then the speed of the meter will not have time to change as the current changes and the meter will have a mean torque proportional to the mean square of the current, and as the voltage is assumed constant it will register proportional to the *root-mean-square* current. But the power taken from the mains is proportional to the mean current, and if the meter has been calibrated with a steady current the meter will always register *too fast* by an amount depending on the ratio $C_{R.M.S.}/C_{mean.}$; a ratio that could be theoretically very large, but in quite ordinary cases might give an error of 5 to 10 per cent.

If a non-inductive shunt is put across the meter the current from the mains divides between the two circuits; but owing to the induction in the bath circuit and series magnet the variation of current and the ratio $C_{R.M.S.}/C_{mean.}$ is less in the meter than in the shunt, but the mean current in the bath circuit is determined by the ratio of resistances only, so the effect of putting non-inductive shunts across the meter would be to decrease any inaccuracies that might crop up owing to rapid variations of load.

In the second class of meter where the torque is proportional to the current, the introduction of inductance into either of the circuits will introduce no error as long as the voltage remains constant, as the current (mean) in each circuit is determined only by the ratio of resistances, and the torque is proportional to the true power.

In the latter part of their Paper the authors show the effect of wave form on the reading of an induction meter. These results can be easily explained. The current flowing in an alternating-current circuit and the pressure across it at any instant can be written as follows :—

$$V = v_1 \sin(pt) + v_3 \sin(3pt + \alpha) + v_5 \sin(5pt + \beta),$$
$$A = A_1 \sin(pt + \phi_1) + A_3 \sin(3pt + \phi_3) + A_5 \sin(5pt + \phi_5),$$

and the mean power over a complete cycle is equal to

$$A_1 V_1 \cos\phi_1 + V_3 A_3 \cos(\alpha - \phi_3) + V_5 A_5 \cos(\beta - \phi_5),$$

since terms involving different frequencies when multiplied together and integrated give zero value. We, therefore, get the result that the total power is the sum of the powers due to the fundamental 3rd, 5th, 7th . . . . . waves, each considered separately, and if the reading of a meter is made independent of frequency it will also be independent of wave form as long as there is no appreciable change in the permeance of the magnetic circuits. We also get the result that, if only the meter reads correctly at one particular frequency and if one of the curves is a sine wave of this frequency, it does not matter how distorted the other is, the meter will still register correctly. That is to say, if the pressure wave form of an alternating-current system is kept a sine wave, then an induction type meter can be used to register the energy on very distorted waves of current such as arc lamp circuits, rectifiers, &c., but this is by no means true where the voltage differs from a sine wave. It would be equally true that for a sine wave of current it would not matter how much the voltage was distorted.

In the cases the authors consider, they are dealing with a non-inductive load, and the shape of the wave is the same for both current and pressure. When the harmonic is superimposed on the fundamental the two waves, according to the above equation, could be considered quite separately as giving power to the resistance. Reversing *both* the current and pressure waves of either component should produce no change in the reading since the power is not altered, and it will be seen in Table II. of their Paper that this is practically the case. The reason it is not absolutely true is that the generator giving the fundamental has also a third harmonic, and that this will be added vectorially to the impressed third harmonic due to

Digitized by Google

the second machine, and will not give quite the same value of the third harmonic when the terminals of the second machine are reversed.

It is seen that in practice the meters always read slow, and the higher the value of the harmonic in the resultant wave the slower the meters read. This is undoubtedly due to the fact that they do not register correctly the power given by the higher harmonics.

The curve herewith was obtained by the writer for an induction meter, tested on a varying frequency at unity power factor. It shows that a meter which was correct at its normal frequency of 50 was 15 per cent. slow at 150 ∿, and 23 per cent. slow at 250 ∿. Therefore, we can tell at once, if we know the composition of any wave, how much the error in reading will be.

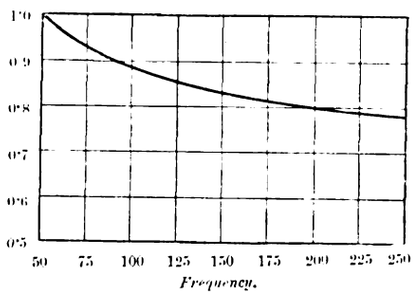
The arrangement the authors adopted in building up their wave was to put two machines in series and to measure the voltage across each machine, the voltage across the two and the wave form of the resultant on load. It is evident in this case that the composition of the wave cannot be judged by the voltage across each machine, since each machine will act as an inductive resistance to the current sent by the other machine and increase the reading of the voltmeters across each, but will decrease the voltage across the two. In this case the only satisfactory way to find the composition of the resultant wave is by analysis. On analysing out wave No. 4 the writer finds the amplitude of the third harmonic about 40 per cent. of the fundamental and the fifth harmonic about 10 per cent., and, therefore, according to the above curve the meter should read

$$\frac{(1\cdot0)^2+(0\cdot85)(0\cdot4)^2+(0\cdot77)(0\cdot1)^2}{(1\cdot0)^2+(0\cdot4)^2+(0\cdot1)^2}$$

of the true energy—*i.e.*, about 2·3 per cent. slow. This gives about the same value as meter A tested by the authors. The analysis of curve No. 5 gives the third harmonic equal in value to the fundamental, and, therefore, the meter would read

$$\frac{(1\cdot0)^2+0\cdot85(1\cdot0)^2}{(1\cdot0)^2+(1\cdot0)^2}=0\cdot925$$

of true value, or 7·5 per cent. too slow, which agrees again with meter A. It is inferred from these curves that meters A and B would



vary with frequency in about the same way as shown in the curve, but that meters C and D would be largely affected.

For the meter tested by the writer the current in the disc due to the current coil was displaced from the flux in the disc due to the pressure coil at normal frequency by an angle equal to the phase displacement of the current and pressure in the mains—*i.e.*, at zero power factor it did not turn, but as the frequency increased the phase displacement became larger, until at 200 ∿ the phase displacement was 11 deg., and the flux in the disc was lagging behind the current in the disc.

These results explain why it is that on an inductive load the meter reads more correctly than on unity power factor; because if a large inductance is put in to make the current lag the inductance has three times the impedance to the third harmonic that it has to the fundamental and, in addition, the phase displacement is greater; so the actual power due to the third, fifth, &c., harmonics is very small, and, therefore, the meter will register nearly correctly. The fact that the flux for the harmonics lags in the disc tends to make the meter read too fast for lagging currents and so compensated at some particular power factor for the reduction in flux in the disc.

If the current in the meter is leading on the pressure the reverse holds, for not only are the harmonics in the current wave exaggerated, but the meter would not read the total power of these harmonics even at unity power factor. As the frequency increases the flux in the disc due to the pressure coil lags more and more, and, therefore, for currents leading their pressure waves by nearly 90 deg. the torque will be negative and will oppose the main torque.

The effect of this is very evident to distributing engineers, as they very often find that at the sending end of a high-tension underground main where there is a capacity current flowing in to the main the meter reads *less than* the one at the receiving end by as much as 10 per cent., and this even when the meters have been carefully calibrated beforehand.

The conclusion to be drawn is that each type of meter should be tested at frequencies much higher than those at which it is to be used, and rejected if not up to a definite standard. The standard need not be a very rigid one. A meter as good as meter B would be quite accurate enough for any practical case, whereas meters C and D would be ruled out.

THE ELECTRICAL EQUIPMENT OF VICTORIA BARRACKS, WINDSOR.

The construction of barracks for the accommodation of troops has of recent years been undergoing many modifications, all of which are for the better. The old arrangement was to provide such accommodation as the canteen, reading and recreation rooms in blocks separate from those in which the men slept. It was usual, too, for the men to sleep, eat and generally live in the same rooms, a not altogether healthy or pleasant arrangement. Further, any provision for sanitary requirements in these older buildings left much to be desired.

The new system of barrack construction is very different from the old, and may be said to be exemplified in the new block which has recently been added to Victoria Barracks, Windsor. These barracks at present accommodate a battalion of Foot Guards, and it is proposed to substitute the accommodation in the new block for that in one of the old blocks, which is to be pulled down. The scheme of the new building has been planned on the basis of accommodating two half battalions, each unit being complete in itself in relation to day, cooking and lavatory accommodation. Both units have, however, the use of the recreation room. The buildings cover an area of 47,600 sq. ft., and consist of two parallel blocks 75 ft. apart, open at the end. The space thus formed between these blocks is roofed over and lighted by large ventilating lanterns, and is used for the dining and recreation rooms. The result is certainly preferable to the old arrangement.

We shall probably be not far wrong in saying that the distinctive feature of the new building is the provision of electricity for lighting purposes. This modern method of illumination has only recently begun to be used by the War Office, but, nevertheless, it is already established on a firm footing, so that all new, and many of the existing, buildings have been, or are being, wired.

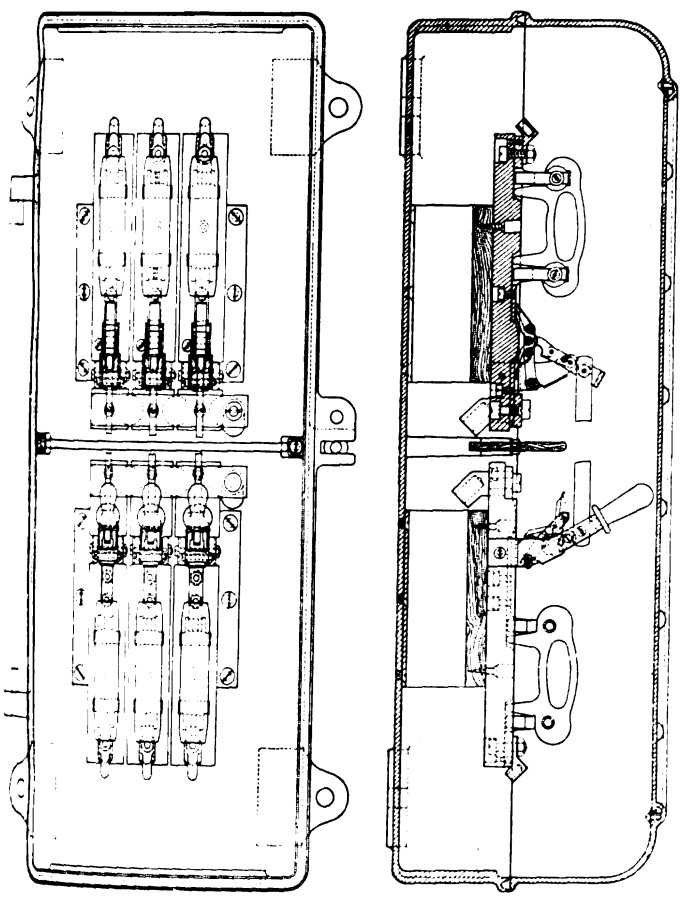
The arrangement of the new barracks in two halves simplifies the wiring scheme to be adopted. Energy is obtained from the mains of the Windsor Installation Co., who supply on the continuous-current three-wire system, the pressure being 220 volts across the outers. After passing through the usual cut-outs, the mains are led into a three-way link box, whence the two lighting circuits are tapped off from one outer and the neutral, while a power circuit for the lift is taken from the two outers. This link box makes it possible to change half the building from one side of the system to the other, if necessary. From this box the two main lighting circuits are divided, and each pass through a double-pole iron-clad switch fuse, which is so arranged that it can only be opened when the switch is "off" and the fuse terminals are dead. The switch cannot be again inserted until the box is closed. The two sets of mains then pass up from the basement to the ground floor, where they are connected in a special switch room to a 13-way double-pole main switch and fuse board, and to an 11-way double-pole main switch and fuse board respectively. Meter bights are also provided in this room. These boards are very well designed, and are contained in substantial iron boxes. The fuses are of the enclosed type, and the double-pole switches, which are worked through links, are arranged to break circuit in two places on each pole. The switch itself consists of a

Digitized by Google

substantial copper brush, which in its off position is entirely dead. When the switch is operated its ends are pressed down against the bus bar on one side and against brass plates on the other, to which ends of the circuit are connected. This obviates the use of terminals on the switches themselves. The switches themselves are capable of breaking a circuit carrying 20 amperes at 220 volts without injury. This arrangement of switches allows the lights to be turned on or off from a central point by the man in charge.. Certain circuits on these boards, too, control "police" lights, which remain on all night for purposes of supervision. A drawing of one of these boards is shown in the accompanying illustration.

As regards living accommodation, the ground floor of the building is divided arbitrarily into two halves, each of which is fed from one side of the three-wire system. On the other floors the division is natural, and is taken advantage of in arranging the mains.

As regards the system of wiring employed, solid drawn steel



Z-Ampere D.P. Switchboard in Cast-iron Case. Scale: One-sixth full size.

screwed tube is used throughout. Not more than 25 ft. of tube on a straight run has been erected without a junction box, while there are never more than two bends between each box. Great care has been taken with regard to earthing. Not only is all the conduit earthed, but arrangements have been made so that all the switch covers and other metal parts are connected through to the conduit. The only case where metal parts are not earthed is when metal shades and lamp-holders on flexible pendants are used. Arrangements are, however, being made to earth these also. The conduit is fixed to the wall or ceiling surface by means of enamelled corrugated metal saddles. These are in many cases of the double type; that is, they support the conduit away from the wall. A universal pattern of junction box has been used throughout. The local switches, too, are fixed inside these boxes, and the latter are in that case provided with domed shape metal covers. This box, besides possessing a universality of pattern, allows individual switches, when a number are mounted together, to be repaired without disturbing the others. The same boxes are used for fixing the ceiling roses, while the back plates of the other fittings and brackets were designed to fasten to similar boxes. Metal filament lamps are used throughout.

The accommodation for which this lighting scheme has been provided would certainly satisfy the most impassioned upholder of the soldier's rights. It may be divided into five sections: Dining and canteen, recreation, day lavatories, sleeping accommodation and accessories.

Two dining rooms are provided, each with accommodation for half a battalion (approximately 500 men). At the end of each room six arches give access to six food locker corridors, which are fitted with a number of lock-up lockers. These rooms are lighted by 60 16 c.p. lamps, arranged on 12 pendants, each containing five lights. One light on each pendant is a police light, and these 12 lights are controlled by 4 special switches. The food locker corridors are each lighted with one 16 c.p. lamp.

It is proposed to use the eastern dining room as a supper and entertainment room, and with this end in view a small but neat stage has been erected at one end. This is lighted by the usual foot and wing lights, the former being fixed on a movable bar so that they can be raised from or lowered into a reflecting trough before and after use. Two small dressing rooms are provided at the back of the stage.

Kitchens, wash-up rooms and service corridors are accommodated along one of the longer sides of the dining room. Here are also to be found a supper cooking room, canteen, and grocery store. The last two have independent access from outside the building for the benefit of soldiers' wives and children. All these rooms are adequately lighted throughout, the lamps being capable of individual control, subject to the system of main control mentioned above.

The recreation division comprises rooms for reading, writing, smoking and games, as well as a billiard room and a room for the corporals. A library is also provided, and this, too, is accessible from the outside. As will be seen from the plan, the corridors give access between the various rooms. These are lighted from pendants, some of which are kept in circuit throughout the night.

The lavatory accommodation is very ample. It is divided into two halves, one of which is placed at the extreme end of each building. This accommodation comprises lavatories, shaving rooms, baths of various sorts, drying rooms and latrines. These places are in general lighted by stiff pendants with a ball joint that allows for movement in a horizontal direction.

Doubtless the most interesting part of these barracks is the sleeping accommodation. Each man is provided with a cubicle, there being altogether 450 in the building. These are arranged in 10 blocks on five floors, three in the southern and two in the northern part of the building, with two N.C.O.'s rooms on each floor and the necessary store adjoining. Each block of cubicles is lighted by 12 16 c.p. lamps, which are controlled from the switches on the distribution boards. Washing and lavatory accommodation is provided at the top of each of three staircases on each floor.

Besides the accommodation mentioned above a number of stores are provided, while small cleaning sheds and a reception station for sick men are provided in separate buildings, and are at present unlighted.

We have to thank Mr. H. Measures, Director of Barrack Construction at the War Office, and Mr. A. Kirk, his assistant, for giving our representative the opportunity of inspecting this installation.

ON RESISTANCES WITH CURRENT AND POTENTIAL TERMINALS.

(*Continued from page 1033, Vol. LXVI.*)

BY G. F. C. SEARLE, M.A., F.R.S.

Summary.—Although conducting systems with current and potential terminals have been in use for many years, the general theory of conduction through such systems has received little attention. The usual proof of the important theorem that current and potential terminals may be interchanged without affecting the P.D. on the main resistance involves the condition that the whole of any one junction is at the same potential. This condition is approximately satisfied in the case of a network of fine wires, but not in a "low resistance" or "shunt." In dealing with such a system we need a proof of the reciprocal relation which shall be independent of the form of the system. Helmholtz has given such a proof, and a simple, direct one is here given due to Heaviside. Dr. Bromwich, employing Green's theorem, also gives a solution. Useful information regarding the properties of conducting systems with three and four terminals is obtained, and it is shown that a triangle of resistances may be replaced for all purposes by a three-rayed star of resistances. In the case of a four-terminal resistance we can construct even low resistance systems such that the want of infinite conductivity at the junctions can produce no sensible error. The discussion of the design of such resistances shows the great advantage of connecting each current and each potential terminal to the main resistance by a rod or wire, the length of such being at least three times its greatest width. The resistance of such a system is very definite. In the case of low resistances capable of carrying currents of the order of 1,000 amperes, slight changes in the connections at the terminal lugs have been found to produce appreciable changes in the P.D. on the main resistance. These defects are easily remedied. Potential "tongues" in sheet resistances are shown to be an advantage. For the comparison of four-terminal resistances with other resistances five methods are discussed, the most important of them being the Thomson bridge, which possesses an advantage not previously realised.

§ 21. *Potential Terminals.*—The great practical advantages gained by placing the terminal screws used in the potential

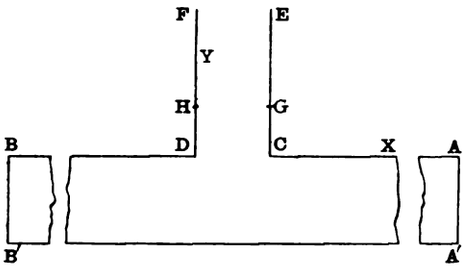

FIG. 15.

measurements at the ends of "potential leads" in the manner indicated in Fig. 13 may be illustrated by the following mathematical example. Let ABB′A′ (Fig. 15) be a strip of metal furnished with a potential lead CEFD of infinite length of uniform thickness t and of uniform width a. Let DA and DF be taken as rectangular axes of x and y. When a current flows along the strip from AA′ to BB′, the lines of flow spread out to some extent into the potential lead, as indicated in Fig. 16, and set up differences of potential between points on that lead. We shall now show how the potential of every point of the lead may be found by Fourier's method when the potential along DC is known.

If V_0 be the potential at any point on DC, we can write

$$V_0=\tfrac{1}{2}T_0+T_1\cos\frac{\pi x}{a}+T_2\cos\frac{2\pi x}{a}+T_3\cos\frac{3\pi x}{a}+\ldots,$$

where the constants T_0, T_1 .... are given by

$$T_n=\frac{2}{a}\int_0^a V_0\cos\frac{n\pi x}{a}dx.$$

The solution of the problem is then given by

$$V=\tfrac{1}{2}T_0+T_1\cos(\pi x/a)e^{-\pi y/a}+T_2\cos(2\pi x/a)e^{-2\pi y/a}+\ldots,$$

where V is the potential at the point x, y. For this quantity satisfies Laplace's equation,

$$\frac{d^2V}{dx^2}+\frac{d^2V}{dy^2}=0.$$

and satisfies the boundary conditions. These are that $V=V_0$ when $y=0$, and that, when $x=0$ and when $x=a$, the current has no component perpendicular to CE. The second condition requires that $dV/dx=0$ when $x=0$ and when $x=a$; and so we see the reason for the choice of the cosine-series for the Fourier expansion of V_0.

Without knowing the value of V_0 at every point of DC, we can find a superior limit to $|T_n|$, where $|T_n|$ is the positive numerical value of T_n. Integrating by parts we see that, when n is not zero,

$$T_n=\frac{2}{n\pi}\left[V_0\sin\frac{n\pi x}{a}\right]_{x=0}^{x=a}-\frac{2}{n\pi}\int_0^a\frac{dV_0}{dx}\sin\frac{n\pi x}{a}dx.$$

Thus, assuming that V_0 steadily increases from D to C (that is, from $x=0$ to $x=a$), we have

$$|T_n|<\frac{2}{n\pi}\int_0^a\frac{dV_0}{dx}=dx,$$

or

$$|T_n|<(2/n\pi)(V_C-V_D).$$

If G and H be two points on CE and DF at a distance y from CD, we have

$$V_G-V_H=-2[T_1e^{-\pi y/a}+T_3e^{-3\pi y/a}+T_5e^{-5\pi y/a}+\ldots].$$

By the inequalities just established

$$\frac{V_G-V_H}{V_C-V_D}<Q,$$

where

$$Q=\frac{4}{\pi}\left(e^{-\pi y/a}+\frac{1}{3}e^{-3\pi y/a}+\frac{1}{5}e^{-5\pi y/a}\ldots\right).$$

When y is not less than a, we see that we may neglect all but the first exponential term. The very rapid manner in which V_G-V_H diminishes as y increases may be seen from the table

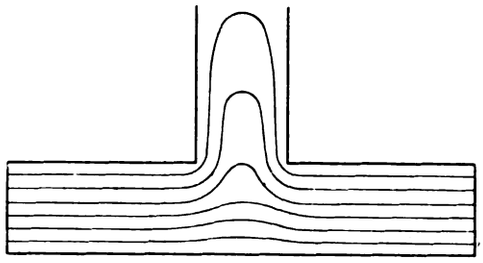

FIG. 16.

in § 20. Thus, when GC is four times CD, V_G-V_H is certainly ess than $\frac{1}{100000}$th part of V_C-V_D. Since the distance between the two potential leads is usually at least 100 times the width of each lead, it will be seen that the differences of potential which can be found between any two points on either lead whose distances from the junctions of lead and strip exceed four times the width of the lead are quite inappreciable compared with the difference of potential between two points, one on each lead.

When the strip ABB′A′ is of uniform width b, except for the potential lead, and AC, BD are great compared with a and b, we can express V_C-V_D in terms of the fall of the potential per unit length at points on A′B′ at a great distance from CD. If the thickness of the metal be t and the specific resistance be σ, this fall of potential per unit length is $i\sigma/bt$, where i is the current flowing from AA′ to BB′. By the Schwarzian transformation it can be shown that

$$V_C-V_D=\frac{4i\sigma}{\pi t}\sinh^{-1}\left(\frac{a}{2b}\right)=\frac{2i\sigma}{bt}\cdot\frac{b}{\pi}\log\left[\frac{\sqrt{4b^2+a^2}+a}{\sqrt{4b^2+a^2}-a}\right],$$

$$=\frac{i\sigma}{bt}\cdot\frac{2a}{\pi}\left[1-\frac{1}{2}\cdot\frac{1}{3}\left(\frac{a}{2b}\right)^2+\frac{1.3}{2.4}\cdot\frac{1}{5}\left(\frac{a}{2b}\right)^4-\frac{1.3.5}{2.4.6}\cdot\frac{1}{7}\left(\frac{a}{2b}\right)^6+\ldots\right]$$

When a/b is small, this gives approximately

$$V_C-V_D=\frac{i\sigma}{bt}\cdot\frac{2a}{\pi},$$

Digitized by Google

so that $V_C - V_D$ is equal to the fall of potential over a length of AB equal to $2/\pi$ times CD.

If the strip be 5 cm. in width and the potential lead be 0·1 cm. in width, while GC is 2 cm., we have

$$V_G - V_H < Q(V_C - V_D) < \frac{i\sigma}{bt} \times 1{\cdot}4 \times 10^{-6}.$$

Thus the greatest difference of potential which can exist between any two points on the part of the potential lead beyond GH is less than that between two points on A′B′ (at a distance from GH separated by the microscopic space of $1{\cdot}4 \times 10^{-6}$ cm.

The Schwarzian process also gives the rather closer limit

$$V_G - V_H = \frac{i\sigma}{bt} \cdot \frac{4a}{\pi} e^{-(1+\pi y/a)}$$

when a/b is small and y is at least equal to a.

When b/a is small the series for $V_C - V_D$ becomes

$$V_C - V_D = \frac{i\sigma}{bt} \cdot \frac{2a}{\pi}\left[\frac{b}{a}\log\frac{a}{b} + \frac{b^3}{a^3} - \frac{3}{2}\frac{b^5}{a^5} + \frac{10}{3}\frac{b^7}{a^7} - \cdots\right].$$

Potential Tongues.—If A, B be the current terminals and C, D potential terminals of a low resistance, the resistance [AB . CD] must be known if the instrument is to serve as a

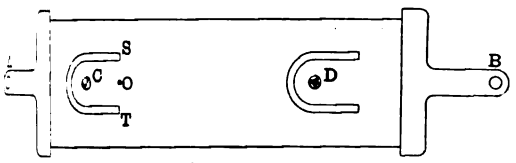

Fig. 17.

standard. The adjustment of [AB . CD] to a definite value can be accomplished in a variety of ways; the most satisfactory method is perhaps that in which potential tongues are employed. A sheet of manganin is attached to two stout copper end-pieces which serve to convey the current into and out of the sheet. Two U-shaped cuts are made in the manganin as in Fig. 17, and the potential terminals C D are attached to the tongues so formed. The resistance [AB . CD] can be adjusted to a definite value by means of these cuts, for [AB . CD] can be increased by lengthening the cuts of the tongue, and can be diminished by lengthening the cuts of the tongue.

In order that the whole of the terminal screw fixed at C may be practically at one potential, it is necessary that there should be no appreciable differences of potential in the parts of the tongue in the immediate neighbourhood of the terminal screw. This condition will be very accurately secured if the length of the tongue be two or three times its width, provided, of course, that the screw is placed near the end of the tongue.

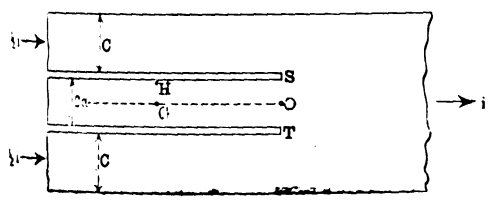

Fig. 18.

If S and T be the ends of the cut of the C-tongue and if O be the middle point of the straight line ST, the straight line OC is a line of flow (provided C is symmetrically placed), and thus we may suppose the tongue to be cut along OC. When the length of the tongue is great compared with its width, we can apply the method of § 21 to determine a superior limit to the difference of potential between two points on the tongue when we know the difference of potential $V_S - V_0$ between S and O. This difference of potential, for a given current between A and B can be found experimentally. If the width of the tongue be $2a$, and y be the distance from ST of two points G H, one on OC and the other on the edge of the tongue, it follows from § 21 that when y is not less than a, we may write

$$\frac{V_H - V_G}{V_S - V_0} < \frac{4}{\pi} e^{-\pi y/a}.$$

Dr. T. J. I'a. Bromwich, F.R.S., has kindly worked out the Schwarzian transformation for the case, in which the potential tongue is of infinite length, as indicated in Fig. 18. If the whole width of the strip be $2a + 2c$, if the total current along the strip be i, and if the slits be symmetrically placed, we have

$$V_S - V_0 = \frac{\sigma i}{2ct} Na.$$

Here N is a number depending upon the ratio of c to a such that $V_S - V_0$ is equal to the fall of potential over a length Na along the parts of width c which are separated from the potential tongue by the slits; the length Na is to be taken at a great distance from S. If we write

$$n = c/(a + c)$$

we have

$$N = \frac{n}{\pi(1-n)} \log\left(\frac{1}{p}\right),$$

where p is to be found in terms of n from the equation

$$\log p = (1-n)\log\frac{n-p}{1-n}.$$

For values of n less than unity the value of p can be found by the process of trial and error. When c/a becomes infinite, the limiting value of N is q/π, where q is given by the equation

$$-q = \log(q-1).$$

Hence, the limiting value of N is 0·4070. The table gives the values of N for some values of c/a.

c/a	n	p	N
1		0·414	0·281
2		0·596	0·330
3		0·692	0·352
4		0·752	0·363
9	$\frac{9}{10}$	0·874	0·386
99	$\frac{99}{100}$	0·987	0·406
∞	1	1·000	0·407

The value of $V_H - V_G$ can then be estimated by means of the former inequality; or by the Schwarzian process we find the closer approximation (when $y > a$)

$$V_H - V_G = \frac{\sigma i}{2ct} Ma$$

where

$$M = \frac{2}{\pi}\left(1 - \frac{1}{m}\right)^m e^{-\pi y/a},$$

if $m = 1 + c/a$ or $n = 1 - 1/m$.

The results obtained by Dr. Bromwich are not strictly applicable to potential tongues of finite length, such as that shown in Fig. 17. In this case the current which enters at A has to

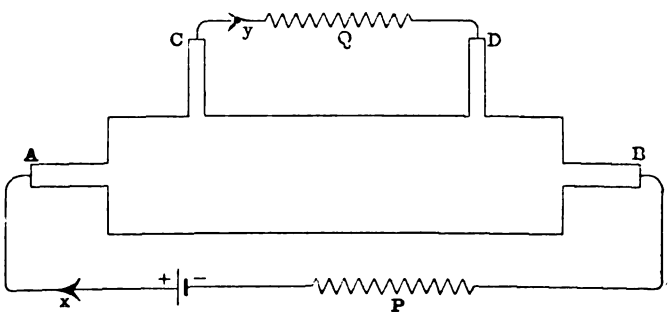

Fig. 19.

divide in order to flow past the U-cut, and consequently the distribution of flow near the sides of the tongue will not be quite the same as in the case considered by Dr. Bromwich. The difference will be more marked as the distance from S (Fig. 17) to the side of the strip becomes large compared with the length of the tongue, but the results will be sufficiently near the truth to give a fairly good idea of the magnitudes involved.

§ 23. *Combinations of a Four-terminal Resistance with Other Resistances.*—We shall consider the case represented in Fig. 19. Here the current terminals A B are joined by a wire of resistance P, in which is inserted an E.M.F. of amount E, the positive pole of the cell being connected to A. The potential terminals C D are connected by a wire of resistance, Q. Let x be the current in the wire P from B to A, and y the current in the wire Q from C to D.

Digitized by Google

Applying Ohm's law to the two wires, we have

$$V_A - V_B = E - Px. \qquad V_C - V_D = Qy.$$

If we consider the conducting system, we see that $V_A - V_B$ is due to the current x, which enters at A and leaves at B, and to the current y, which enters at D and leaves at C. The first contributes x[AB] to $V_A - V_B$, while the second contributes $+y$[AB . DC], or $-y$[AB . CD]. Thus,

$$V_A - V_B = x[AB] - y[AB \cdot CD],$$

and hence

$$E - Px = x[AB] - y[AB \cdot CD].$$

Similarly, from $V_C - V_D$ we obtain

$$Qy = x[AB \cdot CD] - y[CD]. \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Here [AB], [CD] and [AB . CD] are the values which hold good when the wires P and Q are removed.

Solving these equations for x and y we obtain

$$x = \frac{E\{Q + [CD]\}}{\{P + [AB]\}\{Q + [CD]\} - [AB \cdot CD]^2}. \quad . \quad . \quad . \quad (2)$$

$$y = \frac{E[AB \cdot CD]}{\{P + [AB]\}\{Q + [CD]\} - [AB \cdot CD]^2}. \quad . \quad . \quad . \quad (3)$$

Since the last expression is symmetrical with respect to P+[AB] and Q+[CD], it follows that if E had been placed in the wire Q instead of in the wire P, the current in P from A to B would have the value given by (3). Thus, we have the important reciprocal relation :—

If the ends of a wire P, *and the ends of a wire* Q *are connected to a conducting system of any form, an E.M.F. of amount* E *placed in* P *produces in* Q *a current equal to that which an equal E.M.F. placed in* Q *produces in* P.

An important practical case is that in which a voltmeter of resistance Q, is connected to the potential terminals C D of a four-terminal low resistance, the current terminals being A B. From (1) we obtain the relation between the current y through the voltmeter and the current x which enters and leaves the low resistance by the current terminals. Thus,

$$y = \frac{x \cdot [AB \cdot CD]}{Q + [CD]}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

The P.D. between the voltmeter terminals is *not* x . [AB . CD] and *not* xQ[AB . CD]/{Q+[AB . CD]}. The true value is

$$V_C - V_D = \frac{xQ[AB \cdot CD]}{Q + [CD]}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Thus, for practical work with a voltmeter and a standard of low resistance, it is necessary to know [CD] the resistance of the standard measured between the terminals C D, as well as the four-terminal resistance [AB . CD], and hence no certificate granted for the standard is complete unless it gives the value of [CD] as well as the fundamental resistance [AB . CD]. In many cases Q will be large compared with [AB . CD], but if the potential terminals C D are connected to the rest of the system by *wires*, it may easily happen that Q may not be large compared with [CD].

In some cases it may be necessary to make a slight adjustment in the P.D. between C and D due to unit current from A to B. From (5) we see that this can be done by joining the terminals CD by a wire of resistance, Q. If $[AB \cdot CD]_Q$ denote the new value of $(V_C - V_D)/x$, we have

$$[AB \cdot CD]_Q = \frac{[AB \cdot CD]}{1 + [CD]/Q}. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Since [CD] and Q are both positive, it follows that $[AB \cdot CD]_Q$ and [AB . CD] are both positive or both negative, and that $[AB \cdot CD]_Q$ is numerically less than [AB . CD].

We will next find how the resistance between A and B is affected by the presence of the wire Q. The value of $V_A - V_B$ is $x[AB] - y[AB \cdot CD]$, and hence, by (4)

$$V_A - V_B = x\left\{[AB] - \frac{[AB \cdot CD]^2}{Q + [CD]}\right\}.$$

If $[AB]_Q$ denote the resistance between A and B when C and D are connected by Q and P is absent, $V_A - V_B = x[AB]_Q$. Thus,

$$[AB]_Q = [AB] - \frac{[AB \cdot CD]^2}{Q + [CD]}. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Since Q, [CD], [AB] and $[AB]_Q$ are all *positive*, it follows that $[AB]_Q$ is less than [AB] by an amount proportional to the square of the P.D. between C and D due to unit current. Thus we obtain the important result :—

The resistance between two points AB *of a conducting system is diminished by connecting any other two points* C D *by a wire of finite resistance, unless a current entering at* A *and leaving at* B *causes no difference of potential between* C *and* D, *in which case the resistance between* A *and* B *remains unchanged.*

If we solve (7) for $[AB \cdot CD]^2$ we obtain

$$[AB \cdot CD]^2 = \{[AB] - [AB]_Q\}\{Q + [CD]\}. \quad . \quad . \quad . \quad (8)$$

Thus, [AB . CD] can be found when the four two-terminal resistances [AB], $[AB]_Q$, [CD] and Q are known. The *sign* of [AB . CD] depends upon which of the two potential terminals is denoted by C.

If $[CD]_P$ be the resistance between C and D when A and B are joined by a wire of resistance P, the wire Q being absent, we have

$$[AB \cdot CD]^2 = \{[CD] - [CD]_P\}\{P + [AB]\}. \quad . \quad . \quad . \quad (9)$$

Hence, it follows from (8) and (9), if P and Q are adjusted so that P+[AB]=Q+[CD],

$$[AB] - [AB]_Q = [CD] - [CD]_P.$$

In this case the change in the resistance between A and B caused by connecting C and D by the wire Q is equal to the change in the resistance between C and D caused by connecting A and B by the wire P.

§ 24. *Use of Auxiliary Terminals for Shunting.*—In measurements upon a four-terminal resistance with current terminals A B and potential terminals C D, it is sometimes necessary to

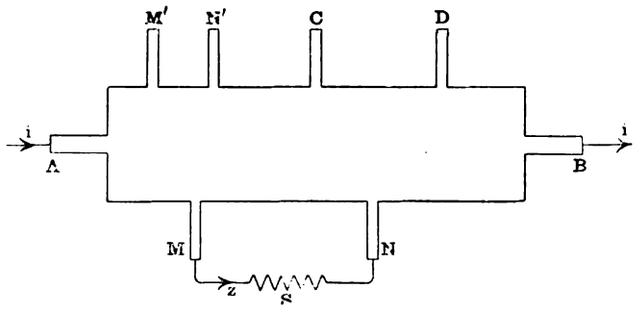

Fig. 20.

make a fine adjustment of the resistance [AB . CD] or [CD . AB] by shunting ; the formulæ are given in § 23. In § 23 the shunt wire is connected to the terminals CD, but it may happen that it is more convenient to attach the shunt wire of resistance S to a pair of auxiliary terminals M N, as in Fig. 20. Let [CD . AB]s be the value of $V_C - V_D$ when unit current enters at A and leaves at B, and M and N are connected by S. Then, if z be the current through S from M to N, when the current entering and leaving at A and B is i, we have

$$[CD \cdot AB]_S i = [CD \cdot AB]i - [CD \cdot MN]z = [CD \cdot AB]i - [MN \cdot CD]z$$
$$Sz = [MN \cdot AB]i - [MN \cdot MN]z = [MN \cdot AB]i - [MN]z.$$

Hence,

$$[CD \cdot AB]_S = [CD \cdot AB] - \frac{[MN \cdot CD][MN \cdot AB]}{S + [MN]}.$$

In Fig. 20 [CD . AB], [MN . CD] and [MN . AB] are all positive ; in this case $[CD \cdot AB]_S$ will be positive and less than [CD . AB] unless the product [MN . CD] [MN . AB] is greater than [CD . AB] {S+[MN]}, when $[CD \cdot AB]_S$ would be negative.

If the auxiliary terminals are at M′ and N′ in Fig. 20, [M′N′ . CD] and [M′N′ . AB] have *opposite* signs ; in this case $[CD \cdot AB]_S$ will be *greater* than [CD . AB].

Thus, if two pairs of auxiliary terminals be provided, it is possible to either increase or diminish the value of [CD . AB]. The maximum change occurs when S is zero and has the numerical value [MN . CD] [MN . AB]/[MN]. Since [MN] is numerically greater than either [MN . CD] or [MN . AB], it follows that the maximum change is numerically less than the numerical value of either [MN . AB] or [MN . CD].

(*To be concluded.*)

PUBLIC ELECTRIC SUPPLY IN COUNTRY DISTRICTS.*

BY W. B. WOODHOUSE.

Abstract.—The author, after discussing the growth of electric supply and the development of the power companies, emphasises the importance of using overhead mains for distributing energy in country districts. Interesting examples of such work, and of street lighting, together with particulars as to cost, are mentioned. The use of electricity on farms is explained.

The history of the electric industry covers a period of some 30 years. In the early "eighties" electricity was supplied for lighting in a small number of towns, and from 1881 to 1883 electric supply companies were registered with a total capital of £16,000,000. In 1882 the first Electric Lighting Act was passed, and its effect on the industry was disastrous, for although 70 Electric Lighting Orders were granted in 1883 under the conditions of this Act, yet nearly all were subsequently revoked, and in 1888 only seven supply undertakings were in existence.

The Act contained three clauses which were objectionable. The first gave the local authority a veto on any application for a Provisional Order, and this veto was in many cases used as a means of extortion from the promoters; the trafficking in Provisional Orders at a later date to be suppressed by the Board of Trade. The second gave the local authority a veto on the use of overhead wires; a third gave the local authority the power to purchase a company's undertaking at the end of 21 years at practically break-up value. The effect of this clause so seriously interfered with the raising of capital that in 1888 an amending Act was passed extending the period to 42 years. From 1888 to 1898 the industry flourished and a large number of Provisional Orders were granted.

The chief effect of output on the cost of production next came to be realised. A large output means low costs, but to obtain this large output it is necessary to supply over large areas. This was the underlying reason for the granting of Electric Power Acts. A Joint Committee of the two Houses of Parliament under the presidency of Lord Cross sat in 1898, and their recommendations were so strongly in favour of supply on a large scale that in 1900, 1901 and 1902 Power Acts were passed for all the important industrial counties in England. Unfortunately for the country as a whole the recommendations of the Committee did not appeal to many local authorities, who set themselves to oppose the passing of the Acts, or to endeavour to have districts cut out from its operations. In some cases the restrictions were so serious that no development has taken place.

The state of affairs when the Power Acts were passed was that many small towns, boroughs and urban districts had taken out Provisional Orders. Some had erected works; others, more fortunate, adopted a waiting policy. The former class found that a small generating station was not always profitable, and, more serious still, that they could not offer so supply power at as cheap a rate as the power companies. Fortunately we learn by our mistakes, and the present tendency now is for local authorities holding Provisional Orders to offer to transfer their powers to a company taking a bulk supply from the power company, or themselves to take the supply. In Yorkshire, when the power company started operations in 1905, there were 25 districts in which local authorities had taken out Electric Lighting Orders. Of these Orders 12 have been revoked by the Board of Trade, seven transferred to a company taking a bulk supply, and four put into force by the local authorities taking a bulk supply from the power company. In not a single case has a small generating station been erected.

The author next referred briefly to the conditions which govern the cost of electricity. In a typical case the total costs are divided in the following proportion: Capital charges, 50 per cent.; coal, 25 per cent.; wages, &c., 15 per cent.; management, 10 per cent.

The capital expenditure on small undertakings is about equally divided between generating machinery and mains it is obvious that a generating station can be avoided, as by taking a bulk supply, expenditure and the risk is immediately halved. The generating plant has to be provided by the power company, but the economies which permit of a cheaper supply being purchased in bulk are: (1) Machinery used in the larger power station costs less per unit; (2) the machinery is more efficient and costs less to run; (the cost of production in a station of 10,000 H.P. will be about one-third of that in a small station); and (3) the machinery can be employed due to the use of current by so many varied industries.

Having then the advantages of generating on a large scale we have now to consider the distribution of electricity. The author confines himself to the consideration of distribution in country districts. In a rural or agricultural district the needs for electricity may be divided under three main heads: Street lighting, cottage and house lighting, power supply to farmhouses.

In such districts as these electricity supply can only be given at a cheap rate by the use of overhead mains. The comparative cost of underground and overhead wires will vary with the nature of the district, but an estimate of the cost of lighting a village street 1 mile long may be of interest. It is assumed that the maximum demand will not exceed 20 kw., and a 4 per cent. pressure variation is allowed for:—

Overhead Wires.

Cost of mains per mile, using wooden poles	£200
Cost of house service (each) and meters	3
Cost of street lamp	2
Mains, with wooden poles	£200
40 services with meters	140
36 street lamps	80
Switching wire for street lamps	10
	—£440

Underground Mains.

Mains	£370
40 services at £5	200
36 street lamps	150
Switching cable	40
	—£760

That is to say, underground mains would cost 75 per cent. more; or, to regard the matter in another way, current could be supplied for private lighting at 1d. per unit less if overhead wires are used. The use of overhead wires in other countries is much more general than in England, and if electricity is ever to be sold at as cheap a price as engineers hope, overhead wires must be used except in the centre of towns.

Objections have been raised to overhead wires on the score of unsightliness; the same argument was used when telegraph wires were first put up, and more recently when electric tramways started. In both cases the wires are more unsightly than the electric supply wires need be. The second objection is that such wires are dangerous. This argument is based on insufficient knowledge of the conditions. Any overhead electric wires erected in this country must be put up in a manner approved by the Board of Trade, and the Board's regulations are so severe, that it is safe to say that in no other country is overhead wire construction carried out in such a substantial and safe manner as in England.

The use of such wires is extending rapidly, and it will be of interest to mention a few cases of their use. The Yorkshire Electric Power Co. has over 90 miles of such lines in use. Low-pressure wires for street lighting are used in a number of towns. In Leeds the street lighting is carried out by means of overhead wires in many of the principal streets. In Barnsley a recent extension of street lighting of a neat and excellent design has been made overhead. In Honley, both street and private lighting is carried out by overhead wires; in Whitwood, the same plan is being adopted.

The lighting of country roads by electricity has many advantages over gas lighting. Freedom from disturbance or flickering due to wind, rain or frost, better distribution of light between lamps and, therefore, more satisfactory illumination and lessened cost are among them. As an example of street lighting carried out by the Yorkshire Electric Power Co. that of Horsforth may be mentioned. The contract for lighting included the provision of the necessary mains, the conversion of existing gas lamps, lighting, cleaning and extinguishing for £2 per lamp per annum. The electric lamps are lighted and extinguished automatically in groups by means of time switches.

Photometric tests of the illumination from these lamps as compared with neighbouring gas lamps showed the following:—

Electric lamp	81 c.p.
Single incandescent gas (new)	68 ,,
Single incandescent gas (old)	35 ,,
Flat flame gas	38 ,,

The Mirfield Council, who are taking a bulk supply from the power company, have converted a number of street lamps to electric lighting on similar lines to those at Horsforth. The number is still growing. The Whitwood Council, who are taking a bulk supply from the power company, are converting all their street lamps to electric lighting—230 lamps in all. The supply will be given by means of overhead wires.

As an example of the cost of equipping electric street lamps, two typical cases are quoted and are given on the next page.

The use of electricity on farms is steadily increasing. Apart from the saving in cost the greatest advantage to the farmer is the fact that power is available whenever needed, and when threshing is to be done there is no delay such as frequently happens when a portable engine is required. Electric power may be tapped from an overhead line at any convenient point; the electric motor may be mounted on a farm waggon and set to drive a threshing machine, a turnip or hay

chopper, a pump, or any of the many purposes for which power is required on a farm. Light and power are both obtainable from the same wires, and the farmhouse and buildings may be well and cheaply lighted. The small first cost of equipment, the general simplicity and ease of operation, and the small cost of upkeep are all important advantages, while the use of electric light in barns and buildings reduces fire risk to the lowest level. Where the need for power is small or infrequent, a joint arrangement between neighbouring farmers may be made to fix a motor at some convenient centre available for all in turn. The healthiness and cleanliness of electric light is nowhere more apparent than in cottages, where roofs are often low and rooms are small.

In a number of cases the power company's supply has been used for cottage lighting, an inclusive charge per week being made for the supply of current and lamps, there being no restriction on the hours of lighting. In one such case a group of 14 cottages is supplied, each cottage being lighted by two 60-watt lamps and two 120-watt lamps. The annual consumption of current per cottage is 160 units. The current consumption is very large on account of the use of carbon lamps. The same illumination from metal lamps would reduce the consumption to 54 units per annum, or 18s. per annum at 4d. per unit. In another case a group of 12 cottages are lighted each by three 16 c.p. tantalum lamps at an annual cost of 15s. 1d. Six other cottages each lighted with four 60-watt lamps use an average of 78 units per annum, costing 6d. a week at a price of 4d. per unit.

Finally, mention is made of the effect of the use of electric power and electric light on the reduction of the smoke nuisance.

THE NON-SALIENT POLE TURBO-ALTERNATOR AND ITS CHARACTERISTICS.

We give below an account of the discussion that took place at the recent meeting of the Birmingham Local Section of the Institution of Electrical Engineers, when Mr. S. P. Smith read his Paper on this subject. An abstract of this Paper appeared in our issue of March 31st.

Mr. A. M. Taylor (Birmingham Corporation Electricity Department) was most interested in the question of regulation. In Table XV. the author gave 15 per cent. regulation with 935 k.v.a. and 28 per cent. with 1,135 k.v.a. Presumably the object was to bring home to engineers how much cheaper it was for a given k.v.a. output to put in a machine having a poor regulation. The reduction of the short-circuit current was closely linked up with this question of regulation, and in fact was the pretext for introducing the poor regulation. Taking the second of the two outputs quoted, the drop from no load to full load would apparently be, in the case of a 5,000 volt machine, from 5,000 to 3,900 volts. If, however, instead of the full load current there was a short-circuit current of, say, ten times this amount, a terminal voltage of zero would be reached (given sufficient time) before the short-circuit current had attained to the dimensions of 4½ times the full load current. No doubt such a drop in voltage as that indicated would not actually occur even with ten times the full load current, owing to the fact that the eddy currents induced in the rotor would prevent the wiping out of the rotor flux. It would be interesting if the author could give an estimate of the actual reduction in voltage that might be expected in, say, the 200th part of a second. Considering, however, that there would be twice the number of demagnetising ampere-turns in the stator that were necessary to reduce the rotor field to zero, it seemed highly probable that the reduction in the rotor flux would be of the order of from 50 to 70 per cent. This raised the point as to whether such a drop, supposing the short-circuit to occur between the generating station and a sub-station, would not be sufficient to throw the rotaries at the sub-station out of step; and before engineers agreed to sacrifice all regulation in the generators at the main station, they ought to be assured on this point.

Dr. M. Kahn (Loughborough) thought the Paper was a useful addition to previous Papers in which the perfect mechanical qualities and the good heat dissipation of the non-salient pole type of rotor had been explained. He wished to mention the name of Charles Brown, to whose inventive spirit they were indebted for the type of rotor in question. The precise mathematical treatment of this type of rotor was to-day of greater importance than ever. The speed of turbo-alternators had been increased considerably in recent years, and machines of 2,000 and 3,000 k.v.a. had now to be designed at 3,000 revs. per min., and 5,000 and 6,000 kw. machines at 1,500 revs. per min. This could only be done if the material in the rotor was used to the best advantage. A very serious consideration in the design of these rotors was the selection of the correct value, β, for the ratio of the wound portion to the unwound portion of the rotor circumference. In the case of two pole machines a value of β of 0·7 to 0·8 would probably be found to give the most economic designs. In four pole machines, a smaller value might often be sufficient to accomodate the rotor winding. The Paper did not show sufficiently what influence regulation had on the size of an alternator. Table XV. indicated that if the regulation were increased from 15 per cent. to 28 per cent. the output was increased from 935 to 1,135 k.v.a. He thought the difference in output would be considerably greater.

Mr. N. Pensabene-Perez (E.C.C.) considered the author's method of investigation was lengthy, tedious and inaccurate. In his desire to decompose the field curve into its harmonics the author had been obliged to assume a very simple trapezium curve by neglecting the M.M.F. steps, the saturation of the iron and the reluctance of the slots. The speaker considered the graphical method, in which it was possible to trace the shape of the flux curve by taking into consideration the above mentioned elements, was much more accurate and infinitely simpler. The effect of slot reluctance in the E.M.F. wave form was very important in turbo-alternators where the slots were generally larger than the teeth. He had had occasion to compare two machines of the axial slot type, built by the Electric Construction Company, one fitted with phosphor bronze wedges and the other fitted with steel wedges. While a larger third harmonic was present in the first mentioned machine, an almost sinusoidal curve was obtained in the other type. Deep steel wedges were most desirable in turbo-alternators, because by doing away with sudden changes of flux density no sudden drop of E.M.F. took place between coils in the adjacent armature slots. This practice also tended to increase the rotor leakage and permitted higher saturation to be reached. The armature leakage was also increased; and this was a very welcome element in turbo-alternators in which short-circuit currents might reach enormous magnitude. He agreed with the author that in the non-salient pole type the E.M.F. wave form was not deformed by the load, but doubted if this constituted a serious advantage. In his opinion the real advantage of the non-salient pole type was purely mechanical, and electrical in so far as it would be possible with such construction to push much further the losses in the field winding, as the cooling of the distributed winding was much more effective, taking place principally by conduction to the iron mass.

Mr. H. W. Taylor (B.T.-H. Co.) felt that although the author's method might be sound, many of the conclusions, stated as of general application to the non-salient pole type of machine, should only be applied to the particular type dealt with. He did not agree with the statement that the leakage of the stator windings was comparatively low in modern machines. He was surprised to see a machine suggested with a regulation of 15 per cent. or even 20 per cent. at 80 per cent. power factor. Manufacturers had for some time been trying to get central station engineers to adopt a machine with coarse regulation, and to have the voltage maintained constant within a small percentage by means of an automatic regulator. The object of this from a designer's point of view was that, owing to the high speed and to the construction that had been adopted to withstand it, a short-circuit on the machine would be very severe and very large mechanical and electrical forces were brought to bear upon the various parts of the machine. Such a machine would probably be cheaper than the close regulating machine by an amount more than equal to the extra price of the regulator. Engineers objected that the regulator might fail; but, while not admitting such a possibility with the perfected regulator of to-day, it might be pointed out that a rise of pressure of 15 per cent. would be as disastrous to lamps and other apparatus on the circuit as the coarsest regulation which designers might offer. It must be remembered further that on large machines the variations in power were small in proportion to the ratings of the machines, so that even without a regulator a hand control of the voltage was quite easy even with a coarse regulation between full and no load. From a practical point of view he was afraid that the scheme of standardisation briefly outlined by the author would not be so simple as might at first sight appear. It need only be pointed out that a manufacturer had to consider the question of standardisation much more broadly and with reference to all his various customers' needs, which included, amongst others, machines for 25, 40, 50 and 60 cycles, low, medium and high voltages; normal and low temperatures rises, &c.

Mr. S. P. Smith, in reply, thought that, with the exception of Dr. Kahn all the speakers had entirely failed to grasp the spirit of the Paper, which was not intended to be a comparison of the cylindrical type of rotor with the salient pole-type. The purpose of the Paper was to bring out a full description of the electrical properties, both good and bad, of the non-salient pole rotor, and this quite apart from its superiority or otherwise. There was no intention to advocate a machine with close regulation more than one with coarse regulation. Mr. Pensabene-Perez did not seem to agree with the method of treatment. It was quite true that the simple trapezium curve had been assumed, which necessitated neglecting the effect of the slots; that this small simplification, however, should make the whole investigation unreliable was absurd, firstly, because the effect of the slots in a case like that in Fig. 2 had very little effect on the *main* shape of the flux or the E.M.F. wave, and, secondly, because in most

Digitized by Google

modern designs, magnetic wedges were used for closing the slots to avoid the prominence of any tooth ripple. Also the objection of Mr. H. W. Taylor that the method adopted could not be applied to every type of salient pole machine had been dealt with in the Paper itself, where it was clearly pointed out that only the general case of the uniformly slotted rotor with a uniform air-gap and a partially distributed winding could be considered.

ELECTRICALLY-DRIVEN REVERSING MILLS AT THE WORKS OF MESSRS. ALFRED HICKMAN.

The rolling mills at the works of Messrs. Alfred Hickman are amongst the largest in the world, certainly the largest yet laid down in this country. They consist of a 30 in. cogging mill and a 24 in. bar mill, and the electrical equipment comprises two reversing mill motors and a flywheel-motor-generator set. The plant presents new and interesting features, since it is the only equipment in which the variable voltage generators and the motors work at ±1,000 volts pressure, and in which, contrary to Continental practice, mills of so large a size are driven by single motors. The driving losses are considerably lower than those which usually occur in plant of corresponding output, and the space occupied is smaller. Under the important head of reversibility, we may mention that when the contract was made for the supply of the equipment a guarantee was given that the time of reversal for each mill motor should not exceed six seconds from the maximum speed in one direction to the maximum speed in the opposite direction. In practice the machines are able to reverse well within this guarantee.

The driving set consists of a motor-generator running at high speed, coupled to a heavy flywheel. The motor-generator transforms the electrical energy supplied by the central station into electrical energy at any voltage from zero to the maximum in either direction, according to the speed and direction required by the mill motor. When the mill motor requires energy for a peak load, then, by means of a special automatic regulator, the speed of the flywheel-motor-generator is allowed to drop, so that the flywheel supplies the extra power to the generator. When the mill motor does not require power, the energy from the central station is absorbed by the flywheel whilst the set is rising to its maximum speed.

The flywheel-motor-generator set (shown in Fig. 1) consists of one motor, two flywheels and two generators, each generator being in direct electrical connection with its own mill motor. Power is supplied from the central station to the motor of the flywheel set at 460 to 500 volts, continuous current. The motor is shunt wound, and is designed to develop 2,000 B.H.P., as a continuous working load. The magnetic circuit of the motor is laminated throughout, so that the speed follows directly any movement of the automatic regulator, described later. The generators are both separately excited, and supply current to the mill motors at a pressure of from 0 to ±1,000 volts. The efficiency of each of the three machines is 94·5 per cent. at full load. Each of the two flywheels is 14 ft. in diameter, and weighs 28 tons, the peripheral speed being about 15,400 ft. per minute; each is built of three separate steel castings only, and is machined and polished to reduce the air friction losses. The maximum speed of the set is 350 revs. per min., which speed may be decreased by means of the automatic regulator to 290 revs. per min.

For starting the flywheel-motor-generator set an arrangement is provided which connects the armature of the cogging mill generator in series with the armature of the motor. This arrangement is economical both in current consumption and in the time required for starting, while it allows a comparatively small starting resistance to be used. The motor of the flywheel-motor-generator set is excited from the 460 to 500 volt 'bus-bars, and an efficient emergency electric brake is obtained by connecting its armature across the starting resistance.

As indicated above, the speed of the flywheel set is made to vary from 15 to 18 per cent. below the maximum in order that the flywheels may supply the power required to equalise the peaks in the load. To obtain this variation in speed, the motor of the flywheel set has a resistance in the shunt field magnet circuit, the amount of this resistance being varied by an automatic regulator operated by the current taken by the motor. This regulator is arranged to come into operation whenever the current input rises above or falls below a predetermined value, and is guaranteed to equalise the load on the generating station to within 20 per cent. of the average load.

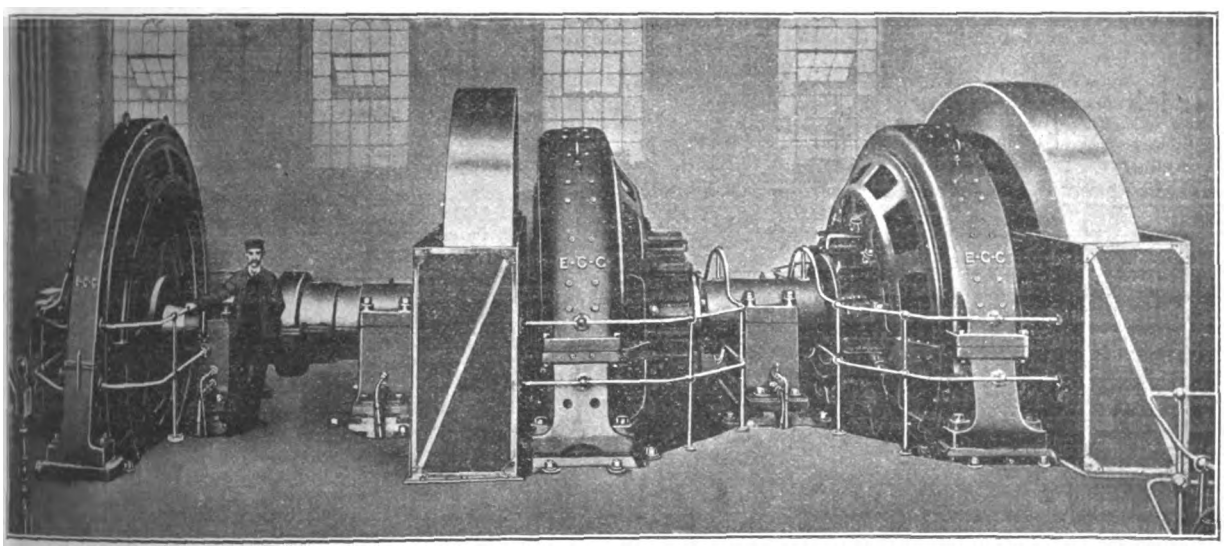

FIG. 1.—FLYWHEEL MOTOR-GENERATOR SET.

The cogging mill and live rolls are used for cogging 2½ ton ingots to blooms of 4½ in. to 6 in. section. The motor is in the same building as the flywheel-motor-generator set, and, as shown in Fig. 2, is connected to the rolls through two-to-one gearing. This motor can develop 4,800 B.H.P. when supplied with current at 1,000 volts for five-second periods six times per minute as a rolling load, and can sustain a maximum load of 9,600 B.H.P. for two-second periods once every hour. The speed of the motor is ± 120 revs. per min., at which speed the output is measured, and it is excited off the 460 to 500 volt circuit. This machine was designed to reverse from +120 to −120 revs. per min. in six seconds, and, as already stated, it has been found in practice that this is easily accomplished. The efficiency of the motor is 94½ per cent. at full load.

Digitized by Google

The bar mill contains two sets of housings and rolls, and is built for rolling sheet bars, billets, rounds, angles, &c. The motor is placed in a light building to protect it from dust and damp, and is connected directly to the rolls. The motor will develop 6,000 B.H.P. for five-second periods six times per minute, and a maximum load of 12,000 B.H.P. for two seconds, once an hour. The speed of the motor is ± 120 revs. per min., and it is excited off the 460 to 500-volt circuit. The reversing tests and efficiency are the same as for the cogging mill motor.

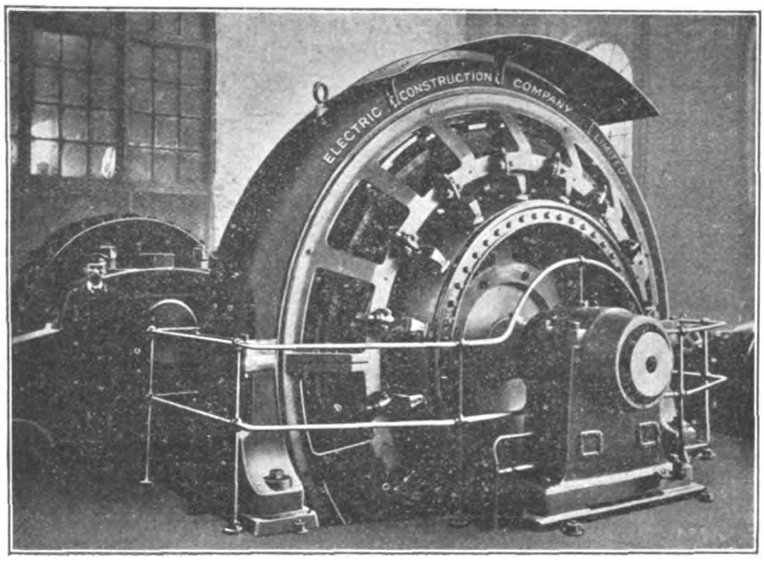

FIG. 2.—BAR MILL REVERSING MOTOR.

The speed and reversal of the mill motors is controlled by a system similar to the Ward-Leonard system, the voltage of the generators being varied between a positive and negative maximum. The voltage variation of each generator is obtained by the operation of a single controller at the corresponding mill platform. This controller varies the field excitation of a small motor-driven exciter, which in turn varies the excitation of its variable voltage generator. Each mill motor has constant field excitation, and the speed therefore depends upon the voltage applied to the armature. Thus each position of the controller handle corresponds to a definite speed of the mill motor. The controller used does not deal with a current greater than 1 ampere. This is obviously a great advantage, since manipulation is easy, and there is no arcing. The vital importance of a good controller for the successful operation of a mill will be readily appreciated, and it is worthy of mention that during two years' continuous work the "E.C.C." controllers in these mills have required no renewals or adjustments, nor do they show signs of requiring such attention. It should be pointed out that with the above system of control only a small amount of energy is lost in reversing the mill, since the energy expended in accelerating the rotating masses is largely returned in the form of electric energy when the speed is decreased.

Circuit breakers are placed in the main circuits in order to safeguard the machines. These breakers are of the "E.C.C." standard type, and are mounted on the main switchboard. Switches, which can be operated by the mill driver or by the switchboard attendant, are provided for breaking the field circuits of the generators. In addition to these safeguards, the connections are so arranged that it is impossible to excite the generator field unless the field of the corresponding motor has been previously excited. Indicators showing the speed of the rolls and of the flywheel motor-generator set are fitted at each mill platform, whilst the speed of the flywheel set can also be read from an indicator on the switchboard.

The exciter set consists of two exciters, direct coupled to, and driven by, one 75 B.H.P. motor. The motor is connected to the 500 volts supply, and runs at a speed of 1,500 revs. per min. The armatures of the two exciters are respectively connected direct to the field circuits of the two variable voltage generators of the converter set. The current in the field circuit of the exciters is varied in magnitude and direction by the position of the controller handle. The magnetic circuits of the exciters are laminated, in order to obtain the necessary quick reversal of flux.

An important point in the equipment of a reversing mill is the control of the live-roll motors. For this purpose we have designed a special controller, which has met very severe working conditions with success. The type embodies the following important features:—The controller is convenient and easy to operate, and is of substantial construction. A long range of speed with even acceleration is obtained. All wearing parts are accessible, and may be quickly renewed. The insulation is suitable for working in the presence of the large amount of metallic oxide dust which abounds everywhere in a rolling mill. In Fig. 3 we give typical current and voltage curves of the cogging mill motor at Messrs. Hickman's, from which the quick reversal of the motor, in spite of the heavy work performed, can easily be observed.

It is satisfactory to be able to give a description of this installation, as it is one more proof of how rapidly the employment of electricity in the iron and steel industry is increasing. For many years it has held the field as the best medium for artificial lighting and for the transmission of power to cranes, roller gear, hot and cold saws and other auxiliary apparatus. But recently its value in the operation of heavy reversing mills has been recognised.

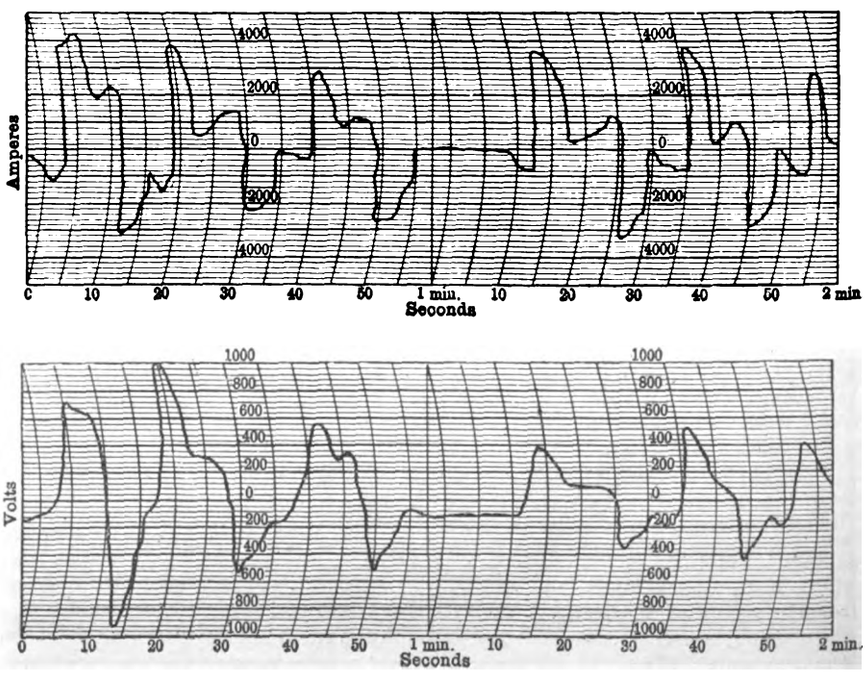

FIG. 3.—TYPICAL CURRENT AND VOLTAGE CURVES OF COGGING MOTOR MILL.

A NEW METHOD OF CHEMICAL ANALYSIS.

The "New Method of Chemical Analysis," on which Sir J. J. Thomson lectured at the Royal Institution last Friday evening, is new only in its application, physical in its method. He deflects the positive rays (the kanalstrahlen of Goldstein) by the magnetic and electric fields, and he thus separates the residual gas in the vacuum tube into a variety of atomic, molecular and complex aggregates or systems; this variety, it will be seen, is greater than would have been expected, and the method, which has some features of spectroscopy, deduces the atomic or molecular weights of the substances from the amount of the deflection. The possibilities of the method [which is also applied in Germany] are astounding; that conclusions will have to be drawn with great caution need not be emphasised.

If electromagnetic field, the lecturer explained, would deflect a positively charged particle in the direction of the ordinate, and the electric field would deflect it in the direction of the abscissæ. If both fields were excited, the particle would be shifted to a point, P, such that $x^2 = Cy$, where C was a constant depending upon the intensities of the fields and the size of the tube. Each particle would produce its own P, and if they were all of the same kind and speed, there would be as many P as particles. But the particles of the same kind do not move at the same speed, and each spot was drawn out into a parabola. They had at first measured the deflections directly on the fluorescent screen of the bulb; afterwards they had made the parabolas photograph themselves on a plate inside the discharge tube. F. W. Aston, his assistant, had constructed a slide shutter box, in which the photographic plate was suspended by a silk thread wound round a top worked in a glass-ground joint. Thus they obtained a series of parabolic curves, and by photographing first with the magnetic deflection directed upwards, and then with the magnetic deflection directed downwards, they obtained full parabolas and determined, on which zero was more easily ascertained. The photographs exhibited were striking. They were produced with the discharge passing through gases at 0·03 mm. of mercury, the gases being nitrogen from the atmosphere, nitrogen from ammonium nitrate, carbon monoxide, carbon dioxide, methane, chloromethane, carbon oxychloride, &c. The general appearance was that of curved streamers issuing from the original position of the undeflected spot, some bright, some faint, increasing and decreasing in intensity in, sometimes heady. Most of the curves were on the expected side where they would be expected; a few faint curves on the other side. Calculating the e/m from measurements of the curve, Sir J. J. Thomson interpreted the curves for atmospheric nitrogen (starting with the positive side) as follows: Positive side: 1·00 H, 1·99 H_2, 6·80 N_{++}, 13·95 N_+, 28 N_{2+}, 39·0 A_+, 101 Hg_{++}, 198 Hg_+; negative side: 1·0 H, 11·2 C, 15·2 O. These figures agreed very closely with the known atomic weights (N = 14, C = 12, A = 40, Hg = 200). The method had the advantage over spectroscopy that it was exceedingly sensitive (0·03 milligramme could be detected), the purity of the substance was of no consequence, since no other substance would only give an additional curve, and results were produced almost instantaneously, so that the successive groups like 12·9 CH_+, 14·05 CH_{2+}, 14·9 CH_{3+} (never isolated before) had been demonstrated. It was intended to study the transformation products of radium in this novel way. Some curves were peculiar; a faint 65·5 Hg_{+++} (?) curve was persistent. Naphthalene and other compound curves 1·5 and 3 (possibly 4) had been found. The curves observed on the negative side belonged to the atoms—hydrogen, carbon, oxygen, chlorine. These curves, notably those of H, also of O, C, Hg were almost persistent, no matter what substance they started from. Quite apart from impurities, however, the analyses demonstrated that a number of atomic and molecular aggregations or systems, single or several charges or uncharged, were always formed. To explain such modifications, including ozone, O_+ and O_{-6}, would account for the different kinds of spectra emitted by the same substance under different conditions; the different kinds give rise to different spectra. That some substances gave on the negative side, indicated that negatively charged particles carried through the kathode, having apparently been struck and attracted by uncharged particles. As these were all in the ultimate condition, it would appear that only the atom, or single, was capable of temporarily exerting a powerful magnetic field. This peculiarity might be connected with the greater freedom of motion in the atom. A magnetic sphere would be like a magnet, because the electricity within it could freely respond to the magnetic induction.

To illustrate his meaning Sir Joseph had mounted a number of needles, each on its vertical pivot, on a piece of cardboard, which was suspended from the ceiling in proximity to the electromagnet. When the electromagnet was excited, the whole system was attracted; but when the needles had been taken off their pivots and placed on the board, there was hardly any attraction. The molecule arising from the combination of atoms which had freedom of motion was a comparatively stiff system in which the bonds were linked. The new line of research promises to help in the solution of the problems of chemical combination.

PHYSICAL SOCIETY.

At the Meeting, held on March 24th, at The Imperial College of Science, Prof. H. L. CALLENDAR, F.R.S., President, in the Chair, an exhibition of a

"Sensitive Thermo-Regulator"

and some

"Experiments on the Measurement of Electrolytic Resistance using Alternating Currents,"

were shown by Dr. H. F. HAWORTH.

The "thermo-regulator" consists of a toluene thermometer with mercury platinum contacts in a capillary tube; these contacts operate, through a Siemens telegraph relay, an electromagnetic switch, which cuts in or out the heating circuit. On account of the very small current required to operate the relay a fine capillary may be used, so ensuring a high magnification with low thermal capacity.

This Paper was discussed by Messrs. Lowry, F. E. Smith and Whipple.

Experiments were also shown illustrating the ease with which a bridge containing an electrolytic cell could be balanced by placing a variable self-induction in series with the cell and adjusting it and the resistance of the bridge simultaneously, as in Wien's experiments, except that a vibration galvanometer was used in place of the optical telephone originally employed by Wien.

The author's deduction from his experiments that the resistance of an electrolyte varies with the frequency of the alternating E.M.F. applied, was discussed by Messrs. Campbell, Duddell, Lowry, F. E. Smith and the Secretary.

A Paper on the "OSCILLATORY CURRENTS IN COUPLED CIRCUITS," was then read by Prof. G. W. O. HOWE. An abstract of this Paper will be found on p. 8 of this issue.

"Some Radio-Telegraphic Apparatus in Use at the City and Guilds College,"

was also briefly exhibited by Prof. G. W. O. HOWE.

The wireless telegraph receiving apparatus was shown connected to the aerial, which is 260 ft. high. A transformer specially designed for experimental work at long wave-lengths was shown. By means of a Brown telephone relay and special trumpets fitted to the telephone receiver, the time signals and messages sent out from Norddeich and from the Eiffel Tower can be plainly heard anywhere in the lecture theatre. The various types of receiving apparatus in use at the College were shown.

Owing to lack of time the discussion on these two Papers was omitted.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" completed Vol. LXVI. With next week's number will be issued (Gratis) the Index to the Volume.

READY APRIL 25th.—Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

ELECTRICITY SUPPLY IN COUNTRY DISTRICTS.

If we are to make good progress towards that time of the universal use of electrical energy, as pictured by Mr. S. Z. DE FERRANTI in his Presidential Address to the Institution of Electrical Engineers, there is no question that country districts must not be left out of consideration. The towns have very naturally received the first attention; and it is perhaps, due to the fact of our towns being very large that our country districts have been left largely on one side The quest, however, for fresh fields and pastures new, as the more profitable parts have become occupied, has caused the supply engineer to turn his attention to the less populated districts.

This subject is discussed in a short Paper read by Mr W. B. WOODHOUSE before the Yorkshire Local Section of the Institution of Electrical Engineers, and from the abstract given on another page our readers will find that good progress is being made in this direction. To the power company the subject is of more than usual interest

Digitized by Google

because the area of such a company is very much greater than that of the usual local authority and necessarily embraces extensive country districts as well as towns. The ultimate aim of the power company should be so to cover its area with mains that electrical energy is available to practically everyone who desires it. If such a desirable state of things is to be reached it is to the power company that we must look, because such an undertaking is better suited for the purpose than is one supplying a small area. The lower cost of the plant, the larger station, and the greater diversity factor all make for lower costs per unit sold. The capital cost of the station per kilowatt having been reduced to a minimum, the cost of mains becomes more than ever a governing factor of the price at which electrical energy can be supplied.

Here fortunately, overhead mains provide a solution of the difficulty and reduce the cost to a very material extent. In the instance given by Mr. WOODHOUSE for the lighting of a mile of village street, underground mains would cost 75 per cent. more than overhead; or, in other words, current could be supplied for private lighting at a penny per unit less if overhead wires are used. Of course, frequent objections have been made to the use of such wires, but these objections cannot be very well supported. Anyone can realise how very much the telegraph and telephone services would have been hampered if overhead wires had not been allowed; and the attempts to prohibit them in these days. In due time, no doubt, following Continental practice, such mains will come into extensive use in this country, and we are glad to see that they are being used increasingly at the present time. Even in such a town as Leeds the street lighting is being carried out by overhead wires in many of the principal streets.

It is interesting to notice how cheaply street lighting can be supplied when such mains are adopted. Thus, the Yorkshire Electric Power Company are charging £2 per lamp per annum at Horsforth, including mains, conversion of existing gas lamps, lighting, cleaning and extinguishing; the electric lamps are of 81 c.p., and are doubtless metal filament. Naturally, such a low price is appealing to the Urban Councils, and further business is resulting.

Apart from street lighting, the use of electrical energy in country districts is required chiefly for the lighting of houses and cottages and for a power supply to farms. It is necessary to effect the lighting of cottages very cheaply if custom is to be obtained, and therefore the system adopted by the Yorkshire Electric Power Company has been to make an inclusive charge for the supply of current and lamps, there being no restriction on the hours of lighting. The removal of this restriction is probably wise, as such restrictions are liable to cause annoyance without effecting any saving to the supply undertaking. In the case cited by Mr. WOODHOUSE the cottages are provided with two 8-watt lamps and two 120-watt lamps (carbon), the annual consumption per cottage being 160 units. In two other cases the lighting is mentioned as being 6d. per week and 15s. 1d. per quarter respectively, with energy at 4d. per unit.

With regard to farmhouses, more seems to have been done on the Continent and in America in giving a supply than in this country. It appears, however, that a distinct demand is arising for power to drive farm machinery, and we do not think there is much doubt that if overhead lines are used freely the British farmer will soon see the advantage of having a supply of power which is always at hand, and from which light can be obtained just as easily as power, although his buildings may be situated a considerable distance from other public means of illumination.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 1d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

The Law Relating to Electrical Energy in India. By J. W. MEARES, M.Inst.C.E., M.I.E.E., assisted by N. N. BLOMFIELD. (Calcutta: Government of India Central Press, for the Author). Rs.10 (15s. nett).

This is an interesting and useful work on the legislation affecting electricity supply in the Empire of India. The law on the subject is now to be found in the Indian Electricity Act, 1910, which repealed, but re-enacted with certain amendments and additions, the 1903 Act. As the author is a practical engineer, and also the electrical adviser to the Government of India, his notes on historical and technical points are of exceptional value. When we reviewed the author's commentary on "The Indian Electricity Act, 1903," we pointed out that Indian legislation relating to electricity supply was in advance of our own, but, frankly, we are disappointed that the electrical industry has not made more progress in India than it has. In the meantime a considerable advance has been made in long distance power transmission, and bulk supply schemes, in the application of electricity to traction, &c., in various parts of the world, and we regret to see that India has not shared to any material extent in this progress. This may have been due to certain defects in the 1903 Act which have been removed by the 1910 Act, but we are inclined to think that the comparatively slow progress of the industry in India is due to the fact that English models were followed on certain points. There was nothing which retarded the growth of electricity supply in England so much as the Electric Lighting Act of 1882, and the effect of that piece of legislation would be even more injurious in India, where the economic, industrial and social conditions are widely different from those which prevail in this country. Consequently, legislation relating to electricity supply which would be quite suitable for this country would be totally inapplicable to India. However, last year's Act seems to be a great improvement upon that of 1903, and we expect that greater progress, especially in traction and power schemes, will be made in future. The principal modifications made by the 1910 Act relate to bulk supply schemes, the regulation of the powers of the Local Governments and the Government of India, the purchase of electricity undertakings, the supply of electricity to districts outside the area of supply and the amendment of licences. In nearly all cases the conditions have been made more favourable to promoters of schemes.

The arrangement of the present edition is practically the same as that of the author's commentary on the 1903 Act, but the book has been rewritten and the information carefully checked. After an introductory chapter, which gives an interesting historical sketch of electrical legislation in India, the author proceeds to give an outline of the general arrangement of the 1910 Act, and to deal with the position of licensed and unlicensed undertakings, the general provisions of the Act applicable to all parties. A useful summary of the law relating to electric railways and tramways follows, and the text of the Indian Electricity Act, 1910, is accompanied by useful notes on clauses, the work concluding with a group of appendices, containing the Rules made under the 1910 Act, general specification for electric wiring, &c. The whole work bears evidence of careful preparation, and it should prove

Digitized by Google

indispensable to companies and engineers connected with electricity supply work in India.

History of the Theories of Æther and Electricity. By E. T. WHITTAKER. (London: Longmans, Green & Co.) Pp. xvi+475. 12s. 6d. net.

This great work grapples with some of the most fascinating and difficult problems that have engaged the attention of workers in physical science during the last three centuries. No reader of ordinary mental calibre can hope to assimilate all its contents; but the book is so ably written that the serious student of average ability will derive great profit from its perusal, and, as the author succeeds in individualising men as well as ideas, the general reader will find much to interest him in its pages.

The headings of the chapters are as follows: I. The theory of the æther in the seventeenth century. II. Electric and magnetic science, prior to the introduction of potentials. III. Galvanism, from Galvani to Ohm. IV. The luminiferous medium from Bradley to Fresnel. V. The æther as an elastic solid. VI. Faraday. VII. The mathematical electricians of the nineteenth century. VIII. Maxwell. IX. Models of the æther. X. The followers of Maxwell. XI. Conduction in solutions and gases, from Faraday to J. J. Thomson. XII. The theory of the æther and electrons in the closing years of the nineteenth century.

The first chapter contains a more lucid account of the earlier theories of light than the reviewer remembers to have read in any special treatise on light. The second chapter narrates the efforts made by Gilbert, Gray, Du Fay, Watson, Cavendish, Poisson and others to develop theories which give results approximating to the facts. The third chapter shows the anatomist, the chemist and the mathematician all engaged in elucidating electrical phenomena. Galvanic and frictional electricity prove to be the same thing; Ampere opens the subject of electrodynamics; and Ohm states a law, which, with a slight modification, is the same as that associated with his name. Chapter IV. pays special attention to polarised light. Chapter V., on the æther as an elastic solid, is very stiff: but it appears to be important, and although the elastic solid theory does not at present hold the position of honour, it is doubtful whether the modern theories of reflection and refraction would have been developed if the great mathematicians of the past had not prepared the way by their ponderous works on more or less imaginary solids. It is a relief to come to Chapter VI. which deals with the researches of Faraday, who was not a mathematician. Succeeding chapters are comparatively modern. They are specially valuable in showing, to some extent, the sources of inspiration of great men like Helmholtz, Maxwell and W. Thomson, and the relative importance of their work. Towards the end of the book the names of men who are happily still with us appear, and anyone who wishes to understand the evolution of the wonderful ideas of J. J. Thomson, and to appreciate the importance and influence of the work of his great contemporaries, cannot do better than study the work under review. A. G.

Modern Lightning Conductors. By KILLINGWORTH HEDGES. (London, 1910: Crosby Lockwood & Son.) Pp. vi.+133.

This book consists partly of the Phœnix Fire Office Rules for Lightning Conductors, but in addition contains much useful information on the subject of lightning which, unfortunately, is not so well understood as it should be. One chapter is a report of the Lightning Research Committee, giving experiments due to Sir Oliver Lodge. The rules are followed by two chapters on Methods of Protection (including Testing) and on Costs and Specifications. Some notes are given on American and Continental practice, and there is a long chapter giving many interesting examples of lightning stroke, illustrated by sketches and photographs. Finally some account is given of the effects of lightning on mankind, upward discharges, fulgurites, globular lightning and other phenomena. The notes that are given contain all kinds of observations and popular ideas, including the essentially American case of a Methodist minister who invoked lightning upon a neighbouring brewery, and was duly sued for the success of his invocation; but whether damages were given against him we are not told. Lightning is one of those interesting subjects that ought to be investigated more closely, but we fear that even an aeronaut would be shy of handling the natural product after reading the experiences of Messrs. Hutchinson & Ward in the heart of a thunderstorm at an altitude of 15,000 ft. in the Alps.

Simmance and Abady's Copyright Tables of Corrections for Harcourt's Ten Candle-power Pentane Lamp. (London: Alex. Wright & Co.)

This book consists of a series of tables printed on strong card and bound together into a folder which can be hung on the wall of the laboratory. The Harcourt standard pentane lamp gives a light of exactly 10 c.p. when the atmosphere contains 0·8 of 1 per cent. by volume of water, and the barometric height is 760 mm. Corrections have therefore to be made in actual practice for both humidity and pressure. These corrections are made by the following formulæ, which are both due to Mr. C. C. Paterson, of the National Physical Laboratory, and have been confirmed by other observers:—

Candle-power $= 10 + 0{\cdot}066\ (8 - \epsilon)$, where ϵ is the number of litres of water per cubic metre of air.

Candle-power $= 10 - 0{\cdot}008\ (760 - b)$, where b is the height of the barometer in millimetres.

The amount of water vapour is determined from readings of a ventilated hygrometer subjected to an air current of minimum speed of 2 metres per second. The tables are arranged in Fahrenheit degrees and inches, though the equivalents on the Centigrade and C.G.S. systems are also given. There can be no doubt that these tables will prove exceedingly useful, while they are admirably designed to withstand heavy wear and tear.

A CURIOUS COHERER PHENOMENON.

BY JOHN HÄRDÉN.

Some time ago the author had the opportunity of observing a curious case of coherer action which may be of some interest.

As is well known, high potential protectors for long distance power lines are often used in which resistance rods of specially prepared carbon mixtures are employed in the earth connection. The phenomenon in question was observed on such rods.

Each rod was a round bar of about ¾ in. by 6 in. to 7 in. in length, with copper plated end caps. They were squirted in a hydraulic press, dried and fired in an electric carbon tube furnace. The mixture used originally was composed chiefly of graphite together with other non-conductive materials.

The resistance value of each rod varied somewhat according to the nature of the power line to be protected and how many were used in series, but as an average they measured about 200 to 250 ohms.

Each rod was carefully tested before passing for delivery, and faulty ones were rejected. In spite of this, grave complaints came in to the office some little time after the first deliveries, all to the effect that rods bought under guarantee to have 250 ohms resistance now showed several megohms. On the return of the rods to the works this fact was verified, yet other unused rods from the same delivery still maintained their proper conductivity.

It was soon found that the faulty rods had invariably been subjected to a high potential discharge, usually of atmospheric or static origin, and consequently a certain amount of current had passed through the rod. To test the effect of this, current was sent through a fresh rod and gradually increased until it was nearly red hot, but this did not cause any permanent change in the resistance.

Tests were then made to imitate the natural conditions, and it was thereby found that one single discharge of oscillatory sparks would cause the resistance to increase to several megohms and remain so. It was of no consequence if the spark entered the rod through the end clip, thus passing through the rod from end to end or if it entered the rod at the middle, the result was the same.

Subsequent tests proved that this remarkable increase in resistance, due to the action of the spark, could be effectively

Digitized by Google

cooled by means of a thick coating of a glassy enamel extended over the whole rod, though not thoroughly eliminated.

On the other hand, if some other poor conductor was used instead of graphite, and a thin enamel coating applied, the above-mentioned effect of the spark was entirely nullified, and no further complaint was heard of since such rods were introduced.

The author has since corresponded in the matter with a prominent and well-known scientist, who expressed his opinion that the phenomenon was a coherer action. No doubt some kind of coherer effect must have been responsible for the behaviour; but it is indeed difficult to explain satisfactorily the actual mechanism of this action. On the one hand, it would be thought that the oscillatory discharge would pass chiefly along the *surface* of the rod only, and the effect of the latter seems to indicate such; but, on the other hand, why should the total resistance of the whole rod be so materially and permanently changed if this was the case?

Again, it is rather strange to note that if the Acheson artificial graphite was excluded, and other non-carbonaceous materials substituted, this action ceased to appear. In any case this behaviour might perhaps be worth some further investigation, as it may eventually throw light on other similar actions.

RADIANT ENERGY AND MATTER.

(Concluded from page 957, Vol. LXVI.)

In the fourth lecture Sir J. J. Thomson referred again to the energy distribution in the spectrum and to the steep ascent and descent of the energy curve in Fig. 3 [the curve is much steeper for higher temperatures]. A little distance off the ordinate of maximum energy the curve was exceedingly weak. In a body at room temperature (say 300 C. abs.) the maximum was at 10μ, in a red hot body (900 C. abs.) at 3.3μ; the latter body would affect a photographic plate intensely in a fraction of a second than the former would require if the exposure lasted as long as the world had existed according to the most extravagant estimate, even if that estimate were multiplied by a million. This calculation assumed that the product of intensity of light and duration of exposure was constant, and that the effective rays were shorter than 0.5μ.

Equations for the very important shape of the curve had been given by Rayleigh; $E_\lambda \propto (\theta \lambda^4)(e^{-\frac{c}{\lambda\theta}})$; Planck, $E_\lambda \propto \frac{1}{\lambda^5} \cdot e^{\frac{c}{\lambda\theta}-1}$; and J. J. Thomson; $E_\lambda \propto (\theta \lambda^4) \cdot I_4^2(c/\lambda\theta)$. The c of the formulæ were the same, and the I was a Bessel function.

Planck's formula was the most generally applied. The experimental confirmation was very difficult; the formulæ agreed, however, in showing that for long waves the energy was simply proportional to the absolute temperature θ, not to θ^4. The formulæ applied to a perfect black body which absorbed and radiated all the energy it received. Such a body was not easily produced, and the relations between absorption and emission required explanation. The latter depended only on the temperature of the body, and if a piece of salt, giving out energy under ordinary conditions, kept its temperature constant in spite of this loss, the explanation was that it received an equal amount of energy. This was known as the "exchanges of Prévost," which had been a necessary forerunner of the wave views, and it was to be understood in the sense, that a man could spend money and yet keep his expenditure equal to his income. The radiation at a certain temperature was equal to the absorption at that temperature, and that held for the whole amount of energy of any special quality of radiation (of particular wave-length). A body placed within an enclosure would ultimately attain the temperature of the enclosure, and the character of the radiation must everywhere be the same within that enclosure. Differences in quality were possible, and there were an excess of blue at the top and an excess of red light at the bottom of the enclosure. A piece of blue glass placed at the bottom should absorb more there and become as warm as the enclosure; shifted to the blue portion, it would absorb less blue light (to which it would be transparent) than it radiated, and should become cooler as it received less energy than it sent out. But such a change of temperature merely by displacement in an enclosure at the same temperature was contrary to all experience, and we hence concluded that the quality of the radiation must be uniform throughout the enclosure, and that the radiation within an enclosure, whatever its nature must be that of a "black body." The name "black" was a misnomer, for the radiating body was bright, and it would be better to speak of "full" radiation. Just because absorption and emission were equal within an enclosure, bodies within it lost all outline, when temperature equilibrium had been attained; when we saw nothing but a glare, looking through an aperture in an enclosure, we knew that constant temperature had really been established. If the universe were of the same temperature throughout it would be invisible, just as a cavity in the glowing coal fire was invisible. This was demonstrated by holding a piece of nickel in a tubular electric furnace by means of a wire; when the nickel was red hot like the tube, it became invisible.

The lecturer then repeated several experiments of Tyndall in exemplification of the relations between radiation and absorption. A Leslie cube, filled with hot water, the right side bright, left side black, was placed between two metal plates, right side black, left side bright, so that black and bright faced one another; the galvanometer joined to thermal junctions was not deflected. For the black surface radiated more than the bright, but the bright opposite reflected more, so that balance was established. If the symbols b and s denoted black and shiny (bright), E emission, and R reflection, E_b being the energy emitted by a black surface, then the black body received energy $E_b = E_s + E_b \cdot R_s$, or $E_s = E_b(1 - R_s)$, or $E_b = E_s/(1 - R_s)$. If A_s further denoted the assumed proportion of the energy absorbed by a reflecting body, such that $R_s + A_s = 1$, we found $E_b = E_s \cdot A_s$, or $E_s = E_b \cdot A_s$. That meant that for any temperature a body (not an ideal black body) would emit as much energy as it would absorb from a black body [or the emissive power of a body for radiation of a certain wave-length is proportional to the absorptive power for the same radiation at the same temperature].

This was known as the law of Kirchhoff (1860), who had drawn the full consequences of the laws of radiation. His old teacher, Balfour Stewart, the lecturer added, had, however, anticipated Kirchhoff in the publication of this law, and it was interesting to mention that the two scientists had independently given some identical experimental confirmations. Thus, tourmaline absorbed light polarised in one plane, but was transparent to light polarised in a plane at right angles to this plane. Now, emission should be equal to absorption, and they observed that heated tourmaline actually emitted polarised radiations. Further, any substance should radiate fully like a black body, if the layer were of sufficient thickness; in the case of glass, however, that layer should be so thick that the glass would appear opaque.

Absorption, the lecturer proceeded, was mostly selective. Glass, which was transparent to ordinary light, would not permit long-wave heat rays of low temperature to pass. In the demonstration a thermopile with two faces was placed between a Leslie cube containing hot water and a limelight. When balance had been effected, a piece of glass was held in front of the cube; the balance was disturbed, while the glass made little difference if interposed between the limelight and the cube. It was generally believed that, owing to this property of the glass, greenhouses became so warm; the glass would catch the sun light as in a trap, not allowing the long-wave rays from the warm moist earth to travel back outside. But R. W. Wood had questioned this, and had shown that there was another chief cause—the glass really imprisoned the air and prevented circulation of the air; if the doors of the green house were left open, the effect vanished. Wood had built himself a small green house of cardboard and rock salt, and had observed an even greater green-house effect, though rock salt was transparent to heat rays, because it allowed more heat to enter.

That some vapours and gases were powerful absorbents of heat Sir J. J. Thomson then demonstrated by old experiments of Tyndall's, partly with Tyndall's apparatus. That water vapour absorbed heat rays had been denied by Magnus, but in the end Tyndall had been victorious in the controversy. A few puffs of ammonia vapour, introduced into a glass tube closed by rock salt discs, also effected a remarkable absorption, which disappeared as the ammonia was replaced by air again, while nitrogen and hydrogen mixed in the proportion so as to make NH_3 had no such effect. Tyndall had also shown that scents like musk absorbed heat rays; but the phenomena were complicated by the presence of water vapour. Carbon dioxide was a powerful absorbent, and Arrhenius had attempted to explain the existence of glacial epochs extending almost to the Equator by the asumption that the percentage of CO_2 in the air had fluctuated. Volcanic eruptions would, in certain epochs, send much CO_2 into the atmosphere and raise its temperature by the greenhouse effect. How a fall of the temperature had been produced, the lecturer did not explain; but he said that a few million tons of CO_2 would bring about temperature differences of 10° C. without necessitating our believing in gigantic forces powerful enough to shift the position of the axis of the earth.

The presence of water vapour in our atmosphere, Sir Joseph continued, in the fifth lecture, was very important meteorologically,

Digitized by Google

It prevented the rapid loss of heat from the earth, and when the air was dry the temperature would fall quickly at sunset. That radiation and absorption were selective had already been stated; it was further demonstrated by placing aqueous solutions of didymium salts in the arc beam. The infra-red was particularly affected by selective absorption. This was investigated by passing a wire bolometer over the spectrum, when sometimes strong deflections and sometimes no current at all were observed. Investigating gases and vapours by this method W. W. Coblentz (Washington) had found CH_2 bands at 3·43, 6·86, 13·6, 14μ; NH_2 bands at 2·96, 6·1μ; NO_2 bands at 7·46 and 9·08μ; C_6H_6 bands at 3·25, 6·78, 8·68, 9·8μ; and an NCS band at 4·78 and an OH band at 2·95μ. It would be noticed that some of these wave-lengths (especially in the CH_2 group) were multiples of one another ($6·86 = 2 \times 3·43$); but these apparent octaves might merely be accidental, for the fine exploring wire was much broader than the line it covered. The method was rather rough, and it might result, that those regularities did not exist any more than the many harmonic groups of spectrum lines, in which we had formerly believed.

If we heated the substance some absorption bands would appear as emission bands, so that something in the vapours must be able to vibrate in series of bands. The relations were not so simple as sometimes stated in text books, however, according to which absorption bands would arise when the body contained a system capable of vibrating at periods corresponding to that of the disturbance passing through it or by it. That was true, but not sufficient. The absorption phenomena were not to be accounted for merely on the tuning-fork analogy. If we had many tuning-forks in a room between the ear and the source of sound, they would enfeeble the intensity of the sound, though strengthening it for people in certain parts of the room; the note was not destroyed, but scattered, and there was a similar optical scattering when light passed through ground glass or through a fog. Absorption, on the other hand, meant definite destruction of the light, a transformation of the energy into something else. It did not suffice that there was something in tune; a mechanism was required which was not light. As a rule the light energy was transformed into heat. The energy absorbed by the sodium vapour was apparently transformed into heat, and that required a mechanism which would work both ways, and would transform heat into light again in the corresponding emission bands. Such emission bands could be produced by heating the substance. But not all lines or bands could be produced by heat; the hydrogen lines, for instance, could only be produced by other means, and, conversely, their light was not absorbed by being passed through hydrogen gas in the ordinary way. In this sense absorption was not always thermal; the light could also produce chemical change or decomposition.

Two demonstrations of such chemical changes were given. In the first the arc light beam was sent through a flask containing amyl-nitrite, when a cloud formed; when the light was first filtered through a flask containing a few drops of the amyl-nitrite a faint cloud was observed, which became much denser when the filter was removed. In the second demonstration, due to C. T. R. Wilson, a beam of ultra-violet light was passed along a tube containing some water and air; the beam was first filtered through a plate of glass, when no cloud appeared. After the removal of this filter for ultra-violet rays the cloud was observed to form, but the effect was weak. This cloud was probably due to the formation of hydrogen peroxide, which had a smaller vapour pressure than pure water, so that a drop once formed would not readily evaporate, but continue to grow in size.

The criterion, Prof. Thomson continued, which should allow us to distinguish between transformation of radiated energy into thermal energy and transformation into chemical separation energy, in cases in which the resulting products could not be collected, was the relation between absorption and emission. A merely thermal change was not a permanent change of the chemical conditions. If no lasting change were effected, the laws of absorption and emission should apply; in the case of a chemical change they would not apply. The radiation of a black body for any wave-length had a maximum at a certain temperature. No substance could radiate more light than the black body, which absorbed and radiated all the energy. If we, therefore, found that a body emitted at a certain temperature more radiation of a certain quality than a black body at the same temperature, then the energy could not be all thermal in that case. But the determination was not by any means so easy as it might be thought. Thus it had been asked, whether the D line of sodium in a salt flame was more intense than the D radiation of a black body. Trying bolometer experiments the lecturer had not been able to decide whether there was any difference in brightness. Paschen had in a series of comparative experiments found, that the D line of sodium salt seemed to be brighter than the D radiation of a platinum wire in the same flame. Quite recently E. Bauer had, however, come to the conclusion that there was no difference. If that were confirmed, we should be justified in regarding the radiation of the sodium flame as merely thermal.

A further question was, whether in a luminous flame or vacuum discharge tube all the sodium or the gas particles were really luminous, or whether the luminosity was confined to a small portion of the total number of molecules. The latter assumption, which seemed to be correct, implied that the luminosity was due, not to the normal molecules, but to systems produced by some agency which excited luminosity. These systems would be few in number. One of the reasons leading to this assumption was found in the connection between the refractive index of a body and the quality of the light it emitted. If light originated, as we believed, in the motion of electrified bodies, then the relations between the refractive index (which was given by the square root of the specific inductive capacity of the body) for waves of infinite lengths and the wave-length of the light emitted should be

$$\mu_\infty^2 = 1 + \Sigma N e^2 \lambda^2 / 4\pi^2 m,$$

where N was the number of particles actually emitting the light (per unit volume), e the charge and m the mass of the particles. The Σ had to be introduced because there would be lines of different wave-lengths, and as spectra were known with hundreds of lines it was clear that only a very small number of the molecules present could actually be concerned in the production of light, especially in consideration of the recent discovery of infra-red rays of very large wave-length. For if all the molecules were to be concerned, the value for the refractive index would become far greater than experiments proved it to be.

The appearance of the spectra themselves afforded further ground in support of this argument. A spectrum was in one respect a very definite thing; it was very constant as to wave-length. But the relative intensities of the lines varied very much with the experimental conditions, and that could be accounted for on the view that special systems of molecules produced the lines, each series of lines being probably emitted by a separate system. The vibration period (or wave-length—not the intensity, of course) was to a surprising degree independent of the temperature.

Going back to the character of the absorption, Sir Joseph repeated that hydrogen gas would not absorb the hydrogen lines, even when under pressure. But it had been shown three years ago that hydrogen would absorb certain lines of the spectrum, the red lines, when a strong electric current was passed through the hydrogen. Thus the electric discharge transformed hydrogen into something abnormal which was able to emit or to absorb the hydrogen lines. It could not yet be said how far these considerations were true for the infra-red; but a few aggregates of molecules only seemed to be concerned in the selective absorption of infra-red rays. The recent experiments of Rubens and Wood on the relative absorptive powers of liquid water and of water vapour suggested that assumption. They found that a layer of water $\frac{1}{2}$ mm. in thickness was opaque to their long waves of $\lambda = 108\mu$, or about 0·1 mm. (method of soap bubbles), while a column of water vapour many feet long, but containing the same number of molecules, would allow one-fourth of the light to pass through. The complex aggregates of liquid water thus seemed to be highly absorptive.

In addition to thermal and chemical changes light absorption might also produce phosphorescence. A phosphorescent substance changed the quality of the light it received. For the demonstration a few crystals of iodine had been put into a large glass flask previously exhausted. At room temperature the flask contained only a little iodine vapour. When the beam of the arc lamp was thrown on the flask, a yellow phosphorescence was seen. This phosphorescence Prof. Thomson said, had been studied by R. W. Wood with monochromatic light, and he had found that the case formed one of the few known exceptions to Stokes' law. According to Stokes, the light given out by a phosphorescent substance was of longer wave-length than the light of the existing source; but Wood obtained light of shorter wave-length.

In the last lecture (April 9th) Prof. Thomson announced that Prof. Rubens had just isolated infra-red rays of $\lambda = 0·3$ mm., so that radiation waves might soon be measured by the foot rule, and the gap between heat and light waves on the one side and electric waves on the other was being bridged over.

Referring then to his own discourse of the previous evening [which we abstract on p. 19], he said that the electric discharge passing through a gas at low pressure disclosed the existence of atoms and molecules with one and more charges, of aggregations like ozone and of more complex arrangement of molecules in great variety; they all seemed to be in special states and, being themselves manufactured by the process which made the gas luminous, they seemed to give rise to the luminous radiations. The different spectra associated with the elements arose from different aggregations,

Digitized by Google

In many spectra the various lines appeared to be associated to several series, principal and subordinate series, the members of which were characterised by a similarity in their behaviour as to fluctuations of pressure, as to the Zeeman effect, &c. Numerical relations between the wave-lengths of these series were first found by Balmer for hydrogen. According to Balmer's law, the wave-lengths of the hydrogen spectrum were $\lambda = Cm^2/(m^2-1)$; all the wave-lengths could be calculated by putting m equal to 1, 2, . . . 32; and although the law was merely empirical, it held so accurately that more reliance was often placed upon the law than upon measurement. The relations were not so simple for other substances, but became simpler when the frequency n (number of vibrations per second) was substituted for λ. Then $n = C'(1-4/m)^2$; here the first value to be taken for m was 3. Rydberg had modified this formula into $n = C - C'/(m+a)^2$, where a had to be determined for each element, while the second constant C was the same for all elements and orders of spectra. Recently W. Ritz had improved the formula by substituting for the bracket the factor $(m+a+\beta/m)^2$; a similar formula formed the basis of the studies of W. M. Hicks [Sheffield]. Ritz and Hicks also) had suggested a physical explanation for the empirical formulæ. Ritz (1908) regarded light as produced by the motion of a negatively electrified particle under the influence of a magnet force. If the particle were situated above a bar magnet (like the dot over the İ), the particle would describe a circle; and since $Hv = m^2 r$ (where r was the radius of this circle), the frequency was H/r m, that is, proportional to the magnetic force. Now if there were only one magnet, the moment would depend, among other things, upon the distance c between the particle and the magnet; if there were a chain of equal magnets, all joined to form a straight line, the moment would depend upon $(1+c)^2$ for two magnets, upon $(2+c)^2$ for three magnets, and so on, and thus the different values for m came in. The Zeeman effect certainly suggested rotation of the particles in the magnetic field. Another suggestion of molecular magnetism had been made by P. Weiss. Each atom was to contain a permanent magnet of the same kind for all the elements, and his magnetic calculations of the vibration frequency of radiations were in fair agreement with other calculations.

Turning to the formation of special substances in connection with luminescence, Prof. Thomson demonstrated thermo-luminescence. Powdered sulphate of calcium and magnesium were put in a little platinum boat which was placed in a glass tube that was sealed with an open end to the open end of a Röntgen tube; this had been done before the lecture. The mixed salts were now exposed to Röntgen rays for a minute or so; the sealing wax was then melted in a small flame, and the boat taken out. It was faintly luminescent, and the luminescence increased at once, when the boat was heated over a burner, to die out again. The Röntgen rays had formed a new unstable compound, which went back to its original state and was luminescent while the transition lasted; the change was hastened by heating. In another demonstration the lower bulb of a dumb-bell tube was placed within a coil joined to a Leyden jar circuit; the bulbs were filled with oxygen. Each spark discharge in the circuit caused the oxygen in the upper (visible) bulb luminous for a little while owing to the formation of ozone; but heating destroyed this luminescence because it destroyed the ozone.

Asking, finally, what was the nature of radiation and of light waves, Prof. Thomson said, one might think of sound. Mathematically the sound compression-waves were very simple things, depending merely on the pressure and velocity of the air. That was sufficient for the theory to explain everything, without any reference to the molecular theory of gases. But the phenomena were more complicated than the theory, which regarded the whole problem as hardly more than merely statistical, like a census. An intelligent molecule would not know on that theory, that a sound wave was passing near to it, and that the molecules (population) were crowded in certain directions. It was only when we had to deal with sounds so shrill that the sound wave became comparable to the free path, however, that the mathematical treatment might not remain adequate. It was similar with light. Everything concerning purely optical effects was explained by a mathematical representation of a light wave, as were other physical effects. When we considered the latter, it was at first sufficient to regard light as something continuous advancing with a wave front; we had to represent light as a series of bright spots on dark ground. For one reason: If all the space which the light traversed were to be filled by the full energy which the light carried, we wanted too much energy; if the energy were all concentrated in spots, we wanted less. We could deduce the maximum electric force and maximum energy in any kind of light; the electric force, we found, was not nearly sufficient for some purely optical effects. For instance. Ultra-violet light falling on a sheet of zinc (or freshly cleaned zinc first) rapidly discharged the zinc when charged negatively, but not when charged positively, nor did ordinary light (ultra-violet rays filtered through a glass screen) produce a discharge. The ultra-violet rays thus caused the negative particles to shoot off at a velocity; this velocity, as well as the electric force required to produce it, could be calculated. But light would have to vibrate at billions and billions of times per second to produce that velocity, unless we conceded, that the maximum energy was greater in spots than it would be with uniform distribution. Another reason: Even the feeblest light would affect a photographic plate, if the exposure were long enough. But the corresponding electric force of, say, 0·00001 volt would produce no effect at all, though its equivalent in the electromagnetic theory of light was optically active. Hence light would appear to be concentrated in spots or specks which would be few in number and widely scattered in weak light.

Concluding, under pressure of time, Sir Joseph mentioned some quite recent experiments of C. T. R. Wilson's, which would not absolutely prove, but support, the just-expressed view. In the well-known old experiment of Wilson a vapour cloud was observed, when ionised air was expanded. The experiment had been improved by using a very accurate piston and by expanding a thin slab of air so as to avoid all eddy currents; it had taken many months to achieve this. When the ionisation was effected by β rays in a strong field and observed in a strong light, Wilson saw a few fine lines like spider threads marking the particles which had traversed the cloud in the moment of expansion. When Röntgen rays (ether waves like light) were used, a series of bright specks, not a uniform cloud, was seen.

CORRESPONDENCE.

LEPEL AND TELEFUNKEN WIRELESS TELEGRAPH PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 3, 1911, is published a decision of the German Patent Office, regarding the application of Herr von Lepel for the revocation of three applications of the Telefunken Co.

As regards these I may perhaps remark that the decision in this matter has been disputed by the Telefunken Co., and that there are still two outstanding points to be dealt with before the transaction is invalidated.

Count Arco has promised to return to the subject only after the Courts have given their decision, and will fulfil his promise. As, however, I am mentioned in the article quoted above as the representative of the Telefunken Co., and am not bound by the same restriction as is Count Arco, I feel it my duty to make known five of the determining decisions of the German Patent Office, which relate to Herr von Lepel's inventions.

1. Decision of the Application Branch of the German Patent Office on July 27, 1910, in the matter of the patent application G. 26,612 (Telefunken):—

Arrangement for the Generation of Electric Oscillations.

The protest L. 24,757 VIII./21a4 made by von Lepel does not invalidate this patent under §3, subsection 1 of the Patent Law. This patent also refers, it is true, to the working of a short spark gap by means of alternating current with Wien's shock excitation, but that is not the subject dealt with in the application. Under the circumstances it is therefore superfluous to decide the further demand of the applicant in the above application as to the validity of the application L. 24,757 VIII. 21a4, and in the meantime publication of the patent by the Application Branch has been determined upon.

2. Decision of the Application Branch of the German Patent Office on October 29, 1910, in the matter of patent application G. 26,744 (Telefunken):—

Spark Gaps for carrying out Wien's Methods for Generating Electric Oscillations.

The prior use claimed by Ruhmer consists of experiments which the applicant carried out in the year 1907 with Lepel's generator. In the publications dealing with application L. 24,757 which relates to the Lepel arrangement the Application Branch has laid down already that this arrangement is not identical with that of Wien. Arco's lecture at Cologne (published in THE ELECTRICIAN for July, 1909) alluded to by the applicant, contains nothing which contradicts the view taken by the Application Branch. It is therefore superfluous to bring in the question of prior use.

3. Decision of the Application Branch of the German Patent

Digitized by Google

Office on October 28, 1910, in the matter of the patent application G. 27,164 (Telefunken) :—

Arrangement for carrying out Wien's Method of Generating Electric Oscillations—Hissing Spark Gaps—in which several Spark Gaps are connected in series.

The application of the "Polyfrequenz" Elektrizitäts Gesellschaft, P. 19,596, cannot be considered as invalidating this patent, for the patent fails on this application, and the complaint submitted has been withdrawn. In this application the grounds of invalidation are not, in the opinion of the Application Branch, sufficient, as they do not deal with the identical arrangement, but with some other. As regards the objection against application L. 24,757 the Application Branch has laid down in the arrangement published that the object of that application has nothing to do with Wien's arrangement. Also that it is not principally concerned with series spark gaps.

The assertion made by von Lepel in his objection of illegal borrowing, rests upon tests which the applicant carried out for the respondent in 1907 with the above-mentioned application L. 24,757 in view. It was afterwards made evident that the object of this application neither concerned an identical spark gap or an identical method. There is, from the Application Branch point of view, no case of illegal borrowing. The same conclusion arises from tests carried out later—namely, those of Lepel, who has the further only "imagined" illegal borrowing.

4. Decision of the Application Branch of the Patent Office on November 5, 1910, in the matter of patent application G. 28,198 (Telefunken) :—

Spark Gaps for carrying out Wien's Arrangement for Generating Electric Oscillations.

The Poulsen lamp indicated in the protest of the C. Lorenz Aktien Gesellschaft is not used for the generation of oscillations in Wien's system, and is therefore not identical with the object of the application.

The same applies to the Lepel spark gap dealt with in application L. 24,757/21a4, as published by the Application Branch, which has nothing to do with Wien's arrangement. The description given by the "Polyfrequenz" Elektrizitäts Gesellschaft of this spark gap in "Electrical Engineering" during 1909, does not affect the question as regards the present application, as it was first published about a year after the date of application.

Also if the use of the Wien arrangement is taken into consideration, then the Lepel spark gap is not identical with the subject of the application, as the insulation lying between the electrodes as mentioned at the end of the application L. 24,757 is not used for keeping the sparking chambers air-tight.

As, therefore, application L. 24,757/21a4 deals neither with the identical arrangement nor with an identical spark gap, there is no occasion for the Application Branch to admit the illegal borrowing from von Lepel of the subject of the above application.

5. Decision of the Application Branch of the Patent Office on June 20, 1910, in the matter of patent application L. 24,757 (v. Lepel) :—

Arrangement for Generating Rapid Electric Oscillations by Alternating or Direct Current.

It should be noted with regard to the oft-reiterated objection to Wien's well-known method of generating shock excitation that in this application there is no mention of this arrangement. On the other hand, in this application short discharge gaps are used which makes it in no way certain that it deals with shock excitations. Further, to generate shock excitations requires, besides the short discharge gap, close coupling of the secondary circuit with the primary circuit containing the spark gap, and this is not the case in this application.

The last quotation makes it clear that the Application Branch of the German Patent Office has explicitly acknowledged that the Lepel arrangement has nothing whatever to do with that of Wien.

If the periodical literature is perused, or that part which has been published by Herr von Lepel, it will be found that this falls into two categories. The first contains all that of date previous to June 4, 1909, and the second all that of later date.

In the first category attention is only paid to undamped oscillations, as will be seen by referring to the following articles in THE ELECTRICIAN, Vol. LX., p. 623, Vol. LXIII., pp. 52, 53, 142, 174, 175, 332, 333.

In the latter publications only Wien's arrangement is mentioned. This division is interesting in so far as, on June 4, 1909, Count Arco delivered his lecture at Cologne, when for the first time the Telefunken Co. came out into the open, and made public suitable arrangements for the practical use of Wien's invention.—I am, Sir, yours &c.,

P. PICHON,
Chief Engineer of the Telefunken Co.

Berlin, March 29.

YORKSHIRE *v.* LANCASHIRE BOILERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 31st you give extracts from a Paper on steam boilers read by Mr. Mountain, the borough electrical engineer for Huddersfield, before the Yorkshire branch of Electrical Engineers at the Sheffield University. Mr. Mountain, in referring to the Yorkshire boiler said:—"There seems to be little doubt that the same evaporation can be obtained from a Yorkshire boiler 24 ft. *long* as from a Lancashire boiler 30 ft. long, shell diameters being equal. The gradual enlargement of the furnace tubes at the back of the Yorkshire enables the gases to pass through the boiler more freely, and consequently with the same chimney draught the consumption of coal *per* foot of grate must be increased."

It is a sign of progress when a prominent engineer like Mr. Mountain has the courage to speak in such a convincing manner, as he evidently quite understands that the contracted rear end of the furnace flues of a Lancashire boiler acts as a permanent brake, which not only keeps down the evaporation but also detracts from the efficiency of the boiler. It is only common justice to the Yorkshire Boiler Co., however, to state that Mr. Mountain has under-estimated the duty and efficiency of the Yorkshire, as a boiler 20 ft. long will give an equal hourly evaporation to that of a 30 ft. Lancashire, and for 8 per cent. less fuel; and four 24 ft. Yorkshire will give an equal hourly evaporation to that of five 30 ft. Lancashire, draught conditions and fuel being equal, maintaining the same efficiency.

I would also point out that at the same meeting the overall efficiency of a 24 ft. Yorkshire boiler and economiser was stated to be 65 per cent. A boiler of this size, however, when evaporating 1,500 gallons of water per hour will maintain an efficiency of approximately 63 per cent., so that with boiler and economiser the overall efficiency would be 73 per cent. A 20 ft. by 8 ft. 6 in. Yorkshire boiler will give an evaporation of 8,000 lbs. of water per hour, and maintain an efficiency of 70 per cent. The same boiler can be worked up to an evaporation of 1,380 gallons, and the drop in efficiency will not be more than 10 per cent.

The thermal efficiency of any boiler depends on the quality of combustion, and this is controlled by thick fires and a powerful draught, such as are secured in a Yorkshire boiler by expanding the furnace flues; hence the reason of this boiler's greater efficiency and evaporative power as compared with the now (from a scientific point of view) obsolete Lancashire.—I am, &c.

Standard Buildings, Leeds, April 3. W. H. CASMEY.

SYNTONY OF A QUENCHED SPARK.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On reading Messrs. Eccles & Makower's answer to me in your issue of March 24, I gather that they are under the impression that my article was based on only one set of observations. If such had been the case my statements of conditions of experiment, which form the premise of my arguments, could scarcely be accepted by them, on account of the character of novelty which they attribute to the phenomena under discussion. As a matter of fact, the measurements mentioned in my article are an intentional reproduction of cases with which I was quite familiar owing to previous observation and experiment.

From my article Messrs. Eccles & Makower arrive at the *theorem* "that the root-mean-square of the current in the receiving antenna is proportional to the simple mean square of the current in the sending antenna." On the contrary, I gave the following experiment:—"Always keeping the same point of relative syntony, an absolutely non-inductive resistance of 0·5 ohm was switched in and out of the aerial, with the result that the *relative variations* of comparative mean square readings of aerial currents were identical for both transmitting and receiving, that is 10 per cent., while the indications of the primary current and supply current ammeters remained unvaried."

This sentence, I believe, is clear, but I am sorry that an error of expression (*ratios* for *relative variations*) on my part should

Digitized by Google

[illegible] Messrs. Eccles & Makower astray. So the *ratios* [illegible] also identical, transmitting and receiving, and equal to [illegible] appeared in the equation

$$(r+H)\,1{\cdot}1 = r+H+0{\cdot}5$$

[illegible] that sentence. Whenever I varied the transmitting [illegible] square aerial current without altering the syntony [illegible] aerial and primary, I produced direct proportional [illegible] at the receiving station on the Duddell thermo-[illegible] meter scale; whenever I altered the syntony I obtained [illegible] which departed widely from the direct proportion.

[illegible] theoretically, the relationship between transmitting and [illegible] current involves three coefficients of energy transfer:—

1. Out of the transmitting aerial = radiation coefficient.
2. Wave propagation.
3. Into the receiving aerial.

To account for the table (THE ELECTRICIAN, page 570) showing [illegible] departure from direct proportion when syntony was [illegible] one of these three coefficients had to change. I [illegible] (3) after investigation (paragraphs 6 and 7, THE ELECTRICIAN, p. 570). I did not take into consideration (2) in [illegible] short distance (8 km.) between the two stations. [illegible] named (1), radiation coefficient.

[illegible] even following Messrs. Eccles & Makower's [illegible] thought, "out of all imaginable causes. . ." it [illegible] have been what they think, a mere assumption on [illegible] to have connected the departures, when syntony was [illegible] from direct proportionality, with variations of radiation [illegible].

However, the transmitting data alone of the experiment [illegible] paragraph 9 of my article and explained again in my [illegible] THE ELECTRICIAN, p. 957), confronted with the experi-[illegible] stated in the sentence which I have corrected, prove that [illegible] radiation coefficient did change with change of syntony.

I believe therefore that I have not committed any fault of [illegible] and if my exposition has been unsatisfactory, I find my [illegible] in Whateley's "*Elements of Logic*": "In all reason-[illegible] which regard matters of fact we introduce, almost at [illegible] step fresh and fresh propositions, which have not been [illegible] in the course of our reasoning, . . . so it is no [illegible] that the longest mathematical demonstration should be [illegible] more easily constructed and understood, than a much [illegible] train of just reasoning concerning real facts."—I am, &c.

[illegible] April 4. R. C. GALLETTI.

WIRELESS TELEGRAPH WORKING IN RELATION TO INTERFERENCES AND PERTURBATIONS.

We give below an abstract of the discussion that took place [illegible] meeting of the Institution of Electrical Engineers last [illegible] Mr. J. E. Taylor's Paper on the above subject. An [illegible] of this Paper appeared in our last issue. An account [illegible] given of the discussion at a meeting of the Newcastle [illegible] Section.

DISCUSSION.

[illegible] C. Loring, R.N. (Inspector of Wireless Telegraphy to the [illegible] Board of Trade), opened the discussion in the Paper headed "Mutual [illegible] between Stations." Mr. Taylor omitted to make any refe-[illegible] to the manner in which he installed the apparatus or the operator who [illegible] to be equipped according to the standard specified [illegible] although there was no reason why there should be any [illegible] between the 600 metre and the 300 metre wave-lengths [illegible] were about 3 miles apart. Last week he had observa-[illegible] station in the Channel of 13 ships equipped with 300 and [illegible] wave-lengths. These were measured by the Marconi mul-[illegible] and the results varied from 1,000 ft. all the way through [illegible] However good the apparatus might be, if it was not pro-[illegible] to cut all kinds of wave-lengths given off, and no amount [illegible] would prevent interference. In the last two years, however, [illegible] great improvement in the fitting of ships, and most of the [illegible] within 5 or 6 per cent. of the 300 or 600 metres wave-[illegible] they were designed. Another difficulty was in regard to [illegible] operators. Some of them were good, some mediocre, and too many [illegible] were due to the rapid development of wireless telegraphy. In [illegible] there had been so many ships fitted that it had been impos-[illegible] to the supply of experienced operators. He was of opinion that the best types of apparatus supplied to ships were in advance of the personnel who were required to use it. For ship-to-shore work the apparatus must remain very simple, and the immediate improvements should take the line of greater simplicity and greater reliability, especially as regards detectors. One of the great troubles was in the receiving apparatus. An operator would not believe his own apparatus was wrong. He always believed "the other fellow's" was. He thought another improvement would be to adopt universally a musical note in transmission. All the operators he had questioned were of the opinion that a musical note would help them very much both as regards the facility of handling traffic and the working through an interference. The note should have a pitch that was capable of variation, and should be aggressive or jarring like the sound of a brass instrument, as opposed to the clear tones of a flute. He agreed with Mr. Taylor that some means of varying the strength of signals was desirable, and the idea of a variable coupling was very good, but he was afraid that an indifferent operator would not make any use of such a device (a variable coupling)—the worse the operator the more he clung to all available power. It was the same with the multiple tuner; the percentage of operators on ships who really understood the use of it was much smaller than it should be. He had collected notes on atmospherics for several years, and he found the worst months were from May to October, especially June, July and September. The best were January, February and March. The worst hours of the day were from sunset to sunrise, and the disturbances were most pronounced at sunset. The best hours were from sunrise to noon. Other things being equal, short wave-lengths say, under 2,000 ft., were less affected by atmospherics than longer ones. Atmospherics appeared to be troublesome on very long wave-lengths all the year round. When two stations equipped with the same type of aerial kept watch on, say, 2,000 ft. and 20,000 ft., the relative hours of interference from atmospherics had been noted on one occasion as 2 to 20. Their Irish stations noted atmospherics to be stronger with a westerly wind, and those on the East Coast of England found they were worst with an easterly wind. Disturbances often seemed to come up with the wind. Hunstanton was remarkable for "freak" signals, which usually occurred on still nights when ordinary signals were of a low strength. They sometimes heard ship stations to the west of Crookhaven, and though the ships lost touch with Crookhaven the signals at Hunstanton still remained strong. They had also got signals from Africa from a ship 2,800 miles distant. North Foreland, Bolt Head and Crookhaven had never inter-communicated, yet they could all communicate, as a rule, with ships in the Mediterranean at night, and the received signals were sometimes as strong as from a ship 20 or 30 miles away. Then there were three stations on the Morocco coast which at one time absolutely jammed the traffic for Crookhaven, but they were only heard at night. Judging from the wide range of the interference at the receiving station, he was sure these Morocco coast stations were not tuned according to the best practice. He had a table giving the number of hours during a year in which atmospherics occurred. These were recorded by two stations which were always in touch with each other. One station gave 670 hours of disturbance: 221 hours of moderate, 285 of strong and 385 of atmospherics in which it was impossible to work, a total of 670 strong to violent atmospherics. The other station working simultaneously and independently gave 658 hours strong to violent atmospherics, which was in remarkably close agreement under the circumstances. The accompanying table showed the number of hours each month that atmospheric disturbances were noted at a station in the Channel:—

Month.	Moderate.*	Strong.*	Violent.*
January	—	—	½
February	—	—	1
March	—	2	—
April	18¾	3	13¾
May	17	43	60
June	13	46½	17½
July	44	52	53
August	20	51	71
September	27	42	94
October	63	25	71
November	15	18	2
December	4	3	2

Sir OLIVER J. LODGE, F.R.S., congratulated the Institution on getting information derived from the valuable experience of those in authority at the Post Office—as in the present Paper and in a previous one by Major O'Meara—information which it was hardly feasible for private people to collect. The whole subject of interference must be of great interest to everybody connected with wireless telegraphy, because in practice they seemed, at present, to be largely dependent on the skill of the operators. The way the latter picked out what they wanted to attend to in the midst of a babel of other communications struck him as very skilful. They managed to do it in times of peace, but he did not know what would happen in war time, when everybody was trying to disturb everybody else. He did not think the Admiralty ought to be satisfied with what might turn out to be a dangerous state of things. He asked Com. Loring whether there would be an insuperable objection to a lower capacity aerial on a ship. At present the custom was for the lower aerial to be the earth—or the sea in the case of a ship. His experience had been mostly gained on land, and he found that when he was using the earth as a lower capacity aerial it spoilt the tuning. Dr. Muirhead had designed an aerial somewhat in the shape of a Maltese cross, which proved an advantageous shape. The wire was brought

* *Moderate*, not affecting signalling; *strong*, signalling difficult; *violent*, signalling impossible.

Digitized by Google

down from the centre, and the individual impulses, after reflection, returned to the centre together and descended the aerial in one complete rush of considerable intensity. On the other hand, in the case of a more ordinary shape, the alternative paths would differ widely and the impulses would descend in a procession. If an earth was employed the impulses went to various depths in the earth, and returned in a procession; moreover, the energy would be dissipated by the resistance of the earth, however well the earth connection was made. At any rate, his experience was that the tuning, though not gone altogether, was greatly vitiated. He expected that this was also the case at sea, where instead of earth they had salt water. The experience recorded in the Paper seemed to show that tuning was very imperfect in most systems. The use of a lower capacity aerial would give better tuning on land, and would also do it on sea unless the sailors objected, or saw no way of fixing the aerial. The Paper stated that there was some difficulty in tuning out a Lodge-Muirhead station; but there ought not to be any such difficulty. Such a station could tune the ships in with their 600 metre wave, or tune them out, at pleasure, but the ships could not tune the station out. They laid the blame on the Lodge-Muirhead system, but he suggested the defect was really theirs. Mr. Taylor interestingly remarked on the difference between what he called a pre-charged system and a system charged by sympathetic resonance worked up in a closed circuit; and he apparently thought the difficulty of tuning out a Lodge-Muirhead station was because of its pre-charged aerial, this having an electrostatic influence on other stations in the neighbourhood—what had been called a "return stroke" in connection with lightning discharges. He (Sir Oliver Lodge) had always doubted that that influence was really an effect of electrostatic induction in the case of lightning, because if one considered how much electrostatic energy there was stored in objects on the earth and what the effect of liberating a small induced charge would be, he did not think it would do any damage. The question now was whether it would effect a coherer. He did not deny that the Lodge-Muirhead station did disturb other stations, but he doubted whether that was the explanation. The coherer did feel the effect, but he suggested that an electrostatic charge was only sufficient to do that if the collector itself was untuned. If a damped vibrator were used as a collector it would take up all disturbances in the neighbourhood and bring them perilously near the coherer circuit, which, although properly tuned, would respond to sufficiently violent disturbances. The disturbance of wireless systems was due to shocks, so to speak, through their untuned collectors. This was not so on the Lodge-Muirhead system. He had experimented with two stations in adjacent fields; one station listening to distant signals was able to tune out the other, although the latter was shouting (transmitting signals to a distance). In another test they split the aerial into two and brought down two wires to two receiving stations. By putting a little different self-induction into the two and using a different lower aerial they could listen with half the aerial to one set and with the second to another set of signals without any interference or overhearing. By that means one got diplex (not duplex) telegraphy. He would be sorry to attempt any of these things if they had an earth connection. They did not generally need the closed receiving circuit, because they had a collector which was very accurately tuneable. One advantage of this was that they had only one thing to tune, and another was that the collector would not respond easily to anything except its own note. The phenomenon of the two wave-lengths was curious, but it was perfectly understood. When you coupled a free vibrator and a damped vibrator together they would not have the same period, or rather if you made them have the same period they would not emit a pure tune, but would emit two tones giving the phenomenon of beats. He could put this mathematically and also show the way to get over it, but he was always giving things away and he was not going to give that away.

Mr. W. Duddell, F.R.S., thought attempts were being made to receive signals using too small an amount of power. If they could use 10 times the amount of power in their transmitters and a corresponding increase in the received energy, all the interferences would become insignificant except those due to other stations, which would remain in exactly the same ratio so that with less sensitive detectors they would be in the same position as now. Present regulations, which tended to tie engineers down to use less power, were really in the wrong direction. It was marvellous that such good results were obtained with such small amounts of energy in the receivers as a fraction of a microwatt. The author had referred to the multiple tuner of the Marconi Co.; he (Mr. Duddell) had always had a difficulty in seeing what was the electrical advantage of this type of apparatus. What was really wanted to obtain good tuning in the receiver was a very freely oscillating circuit and some means of connecting the detector so that it would not introduce too much damping into the circuit. That was all that was effected by the multiple circuit methods. He thought any means by which they could uncouple the detector from the oscillating circuit would give sharper tuning. He asked, Did atmospherics propagate themselves with the velocity of light, and if so, could the direction in which they came be investigated? Was it possible to determine the difference of time between the arrival of an atmospheric at places some hundred miles apart? If one transmitted from a station a "dot" at the time an atmospheric took place, and the atmospheric and the dot were recorded at a receiving station, then with the next atmospheric the experiment was repeated in the opposite direction, one might get some indication of the rate of propagation of the atmospheric. It was stated that long waves were much more affected by atmospherics than short waves. Did it apply to the same station with a short aerial for both the short and long waves, or was it a comparison between stations with small and large aerials? There was no doubt the pre-charged aerial did tend to upset the ordinary coupled receiving station, but, on the other hand, the Lodge type of aerial with insulated lower capacity aerial seemed to be able to tune out the ordinary stations fairly well. He asked Sir Oliver whether that was connected with the shape of the waves sent out by these systems. He thought the large upper capacity and the lower capacity connected together by a self-inductance formed an extremely good oscillator and sent out waves (current) as shown in the accompanying sketch (Fig. 1). On the other hand, the coupled circuit sent out an oscillation of the type illustrated in Fig. 2 herewith. The first oscillation of the directly charged aerial was very large. That, however, did not seem quite to account for the whole difference. An aerial such as that used by Sir Oliver with a large amount of inertia between the upper and lower capacity was little affected by a small but prolonged force slightly out of tune such as one got from a coupled transmitter. Most of the coupled receivers were generally coupled moderately tight. They could not work very loose, or they would not receive enough energy. They could thus get two periods in the oscillating circuits, which would upset the coupled receiver. The coupled receiver was not able to cut the Fig. 1 waves out, but the Lodge aerial was able to cut out the waves

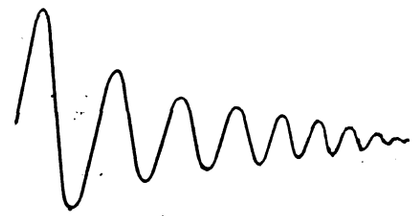

Fig. 1.

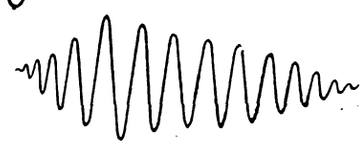

Fig. 2.

emitted by a coupled transmitter. He asked Sir Oliver whether that was the reason why the pre-charged aerial affected receivers of the coupled type more strongly than others. The direct electrostatic action could not be the real explanation because the difficulty occurred over distances of a mile or two.

Sir Oliver Lodge said he thought Mr. Duddell had given the right explanation. He imagined it was the same explanation that Mr. Taylor had intended to indicate in the Paper. Experience showed that the Lodge-Muirhead system was efficient over fairly long distances, because the Indian Government had officially reported its successful use for years between Burma and the Andaman Islands—over 300 miles—less than ½ H.P. being sufficient power. He did not altogether acquiesce in Mr. Duddell's remarks about the desirability of applying very great power. He would prefer to recommend accurate tuning and moderate power. He did not like the idea of everybody shouting at the top of their voice. He would rather speak distinctly, without energy, and discriminate between different recipients.

Although the ordinary Lodge-Muirhead was what Mr. Taylor called a pre-charged system, they were not limited to that. They had another plan which had not that characteristic—the disruptive rush method of charging—which was roughly shown in the following diagram (Fig. 3). They had not had so much experience of this arrangement as of the other, but he would be glad for Mr. Taylor to come and see how far it overcame the objection the Post Office and the Admiralty apparently felt to any pre-charged system. It was unfortunate that they were unable to tune out such stations, though every Lodge-Muirhead station could tune others out easily.

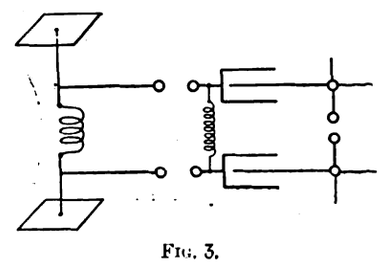

Fig. 3.

Dr. J. Erskine-Murray said he did not think Mr. Duddell had drawn his diagram quite correctly. When he (Dr. Erskine-Murray) was in charge of the Marconi station at Chelmsford, 12 years ago, he found that when a transformer was used as the primary source of power the charge slowly increased before the spark occurred, and thus the current changed from a low to a high frequency at the maximum voltage. The impulse occurred as shown in Fig. 4 herewith. It did not seem to have occurred to Mr. Duddell or Sir Oliver Lodge that signals might be received from the part of the curve marked "*a*." The speaker and Mr. Andrew Gray frequently got signals between Harwich and Chelmsford from this primary charge of the aerial when no oscillatory discharge occurred at all; the charge simply leaking back to earth through the secondary of the induction coil. The author had spoken of blunt resonance curves. He did not think Mr. Taylor had emphasised sufficiently the fact that a blunt resonance curve did not necessarily represent an impure wave. Although a receiver responded for quite a considerable range of variation of its natural frequency it should not be concluded that the waves from the transmitter had a large variety of frequencies. The fact was that there was as a rule only one wave, having one definite frequency, transmitted; but owing to its damping, and to that of the receiver, it was able to excite current in the receiver, although the latter was considerably out of tune

with it. The same was true of the double hump curve. Two definite ... arrived through the ether, but each could excite the receiver ... the latter was somewhat out of tune. The blunt resonance ... this represented shock excitation of the receiver throughout a con... range of frequencies by the action of a damped wave-train of one ... only. He had not found quenched sparks difficult to tune out. ... Company had had reports recently from ships which had com... with a quenched spark station in Jamaica, stating that they ... tuning extremely sharp. He might add that he had found this ... true in his own experience, except at very short distances. At the ... there were disturbances, but at the ordinary working distances the ... was so sharp that Marconi ships could always pick up the quenched ... station, although some of the other ships could not do so. Per... there was too much resistance in the receivers of the latter. In ... to tuning with continuous waves, he thought if everyone stuck to ... waves, which Mr. Duddell showed them how to produce, the con... wave was an extremely good method. The trouble was that they ... produce as much high frequency energy as possible from an arc ... the arc by means of a magnet and other methods, thus causing ... of complex waves. He illustrated roughly by sketches ... between the type of wave obtained in the arc under ... circumstances. Dr. Burstyn told him that seven harmonics ... obtained from the ordinary Poulsen arc, a fact which he had ... confirmed. He thought one cure of atmospherics was the use of ... aerials. Waves came from all directions, and therefore a ... aerial picked up fewer than a non-directive aerial. He was ... to try an aerial with larger capacity as Mr. Duddell suggested. He ... there was not the slightest doubt a large number of " X's " were shock disturbances due to thunderstorms at a distance. Their experience at the Haven proved this. He did not think they could avoid the other kind of disturbance—the frizzling and frying noises which were more or less continuous, and were probably due to ordinary brush discharges from the top of the aerial. The long wave stations were obviously most affected by ... disturbances, which comprised very long waves even if very ... damped. Prof. Fitz Gerald had pointed out that there was a ... that they might get oscillations if the outer part of the atmo... sufficiently conductive. In conclusion, he would be glad if ... would expand the definition of the *coefficient of mutual dis...* between stations, as a fuller understanding of the factors con... led to a search for more definite information as to methods ... the trouble.

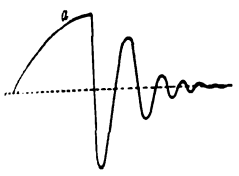

Fig. 4.

A. S. M. SÖRENSEN *said* that with reference to the question of inter... between Poulsen and spark stations he had no experimental data ... but the following points should be observed. The Poulsen ... as such, possessed in a high degree those desirable qualities *for* ... interference advocated in Mr. Taylor's Paper. In favour of ... were the comparative smallness of amplitude, the con... of the waves and the sharpness of tune. In this connection it ... remarked that although the oscillations taken *singly* were not ... by a pure sine curve (due to the arc being extinguished ... oscillation), yet as the damping was generally referred to as ... between amplitudes of consecutive oscillations, and as the ... generated a train of continuous and *uniform* oscillations, the ... damped " seemed not altogether out of place. Further, the ... transmitter only produced audible signals, when a special device ... Poulsen's Tikker), and the small difference between signalling ... wave was only detected by sharply tuned receivers. For ... great freedom from interference should be expected with ... system. At the discussion at Newcastle Mr. Taylor had said ... because the Poulsen system of causing interference over any ... but only meant that the hissing noise might start inter... inside a circle of the order of a mile. In this case the sus... expressed in Mr. Taylor's Paper did not seem well justified. If ... however, was not sufficient freedom, the speaker would suggest a ... To abandon the spark method and adopt the Poulsen system ... at.

W. E. TAYLOR, in reply to the discussion, said that Com. Loring ... some very useful information in regard to the wave-lengths ... and as to atmospherics. There was a great difference ... various types of musical note transmitted, as regards their ... penetrate atmospheric and other disturbances, but no doubt ... or trumpet note was a good one, although he (Mr. Taylor) ... "scratch" took a lot of beating. With regard to what ... had told them, there was no doubt much could be said ... about the earth connection. He surmised that a good deal ... depended on how it was made. Mr. Duddell wanted liberty to use ... amount of power, but the understanding reached by the ... Radio-Telegraphic Conference had to be considered. With ... Mr. Duddell's suggestion as to the time intervals of atmos... changes, he did not quite see how they were to get accurate ... of a 10,000th part of a second at stations 1,000 miles ... possibly it might be done. There had been a little mis... as to what he had meant by " forced oscillations." What ... meant was that a pure sine wave might become distorted ... was fed from a high-tension source of current. His ... if you had pure sine waves, due to a non-damped oscilla... of which was simply oscillating without dissipation, and then began to drive with a direct source of current you would have an impure wave which would produce a different effect on a non-damped receiver from that which would be produced by a pure sine wave. That was what he intended to convey by his remarks on the plain aerial system of transmission. He was glad Mr. Sorensen had come to the conclusion that the Poulsen system was the system of the future, which was not going to interfere with anybody. With regard to interference between continuous wave systems and spark systems, one would, at first sight, suppose they would work together harmoniously. In practice, however, that did not quite turn out to be the case.

DISCUSSION AT NEWCASTLE-ON-TYNE.

Prof. H. STROUD believed that the disturbances due to atmospherics were less pronounced when using the undamped wave system.

Mr. A. S. M. SÖRENSEN (Cullercoats Station) had never heard any complaints that the Poulsen station interfered with others.

Mr. H. KEMPE (G.P.O.) related some experiences he had had when assisting Mr. Marconi.

Mr. H. MORRIS AIREY said that the Armstrong College was only some 8 miles from Cullercoats, and they had thus ample opportunities of testing for interferences. He had found, however, that it was only by the most careful tuning for the known wave-length that it was possible to detect that the Cullercoats station was working at all. Dr. W. H. Eccles and he had spent a considerable amount of time last summer in studying atmospherics, when these were at their worst. Observations were taken during the morning and at night over a period of three months. The actual number of atmospherics was not counted, but the character and intensity of each atmospheric was noted. Observing stations were situated in London and Newcastle, and their watches were synchronised by means of the time signals sent out from Norddeich, Eiffel Tower and Poldhu. Over 70 per cent. of the atmospherics observed corresponded individually: thus, if a long rumble was heard at one station a corresponding rumble was heard at the other. It was concluded that most of the disturbances were not due to local weather conditions, but to discharges taking place in the upper atmosphere and at a very great distance from both stations. He thought that it would eventually be proved that these atmospherics were connected with magnetic disturbances, and that they had the same common origin—*i.e.*, the arrival of negatively charged electrons from the outer space into the earth's atmosphere. The wave-length to which a receiving circuit was tuned had a great influence on the number and character of the atmospherics detected. He had experimented with receivers on the same antenna, but tuned to 2,000 and 600 metres respectively. He asked Mr. Taylor if he had made any observations regarding the connection between atmospherics and the state of the weather. He was inclined to think that disturbances were not liable to occur with a cirrus sky.

Mr. J. B. JOHNSON (G.P.O. Telephones) pointed out the desirability of running sheathed telephone wires into wireless telegraph stations. The open wires originally run between the Cullercoats station and the Whitley Bay exchange were a continual source of trouble, due to false calls and the heat coils operating. Substituting rubber-covered cable made no improvement, and the only cure was found to be a lead-sheathed cable run right into the building.

Mr. B. A. ROBINSON confirmed that some of the atmospherics detected at Cullercoats were tuned and others were not.

Mr. J. M. ROBB (G.P.O. Telephones) said that so far as telephones were concerned, telegraph wires were analogous to pre-charged aerials, and the effects were not unlike those met with in wireless telegraphy. He asked if it was probable that a proportion of the unexplained failures of telephone lightning arresters was due to wireless telegraphy.

Mr. A. L. E. DRUMMOND (National Telephone Co.) said that atmospherics gave trouble analogous to that met with on telephone systems having an earth return.

Mr. A. PATTERSON (P.O. Telegraphs) said that many years ago he was associated with Mr. Taylor in connection with the first wireless telegraph installation in this country. The system had parallel wires, and suffered from atmospherics, sometimes for weeks on end. It invariably became troublesome during stormy weather, and a current of 2 to 3 milliamperes was generated in the receiving wire by the tide, the direction depending upon whether the tide was rising or falling. A similar phenomenon was mentioned in a book on cable testing by Wilson and Purdie.

Mr. C. VERNIER (Newcastle Power Supply Co.) thought that the Poulsen system was less complicated than the spark system, and that it had many other advantages. He suggested enclosing the spark contacts in a metal box, instead of shunting by a condenser as proposed under " Local inductive disturbances." Regarding the origin of atmospherics he asked if these could not be traced to lightning storms in the tropics.

Mr. TAYLOR, in reply, said that he preferred to get a good " scratchy " note in the receiver, as this made the signals easier to read. It was possible to get a slightly hissing note by tuning up the receiving circuit. He had been quite unable to connect atmospherics with local weather conditions. Wireless telegraph working might account for the failure of telephone lightning arresters, but these would have to be very near the station, and in the case of systems using the " precharged " aerial they would have to be within the influence of the electrostatic field. He agreed that there was probably some common factor in atmospherics and magnetic storms. The Poulsen system was useful for certain purposes, but could not be worked from a few dry cells; and on account of the amount of power required it was not suitable for installations in inaccessible places. Regarding the suggestion that disturbances might be due to storms in the tropics, he pointed out that one characteristic of disturbances was that they had a diurnal variation.

CHARGES FOR ELECTRIC ENERGY AT LEEDS.

Last week the City Council made some reductions in the prices charged for electricity for power and heating.

In a report on the subject it was stated that the lowest price now charged for power was 0·8d. per unit (less 5 per cent.) and it was advisable to reduce the minimum price. It was also suggested that the concessions should not be entirely limited to the class of large power consumers but that the opportunity should be taken to offer concessions to other consumers. With the exception of the largest users, the prices for power were based upon the maximum demand system. In the early stages of the business such a system was very advantageous for two reasons. Firstly, the cost of furnishing a regular supply for long hours was less than the cost of furnishing an intermittent supply. Secondly, the forms of power with which electricity had to compete were much more economical in the case of steady loads. In the case of intermittent loads the advantages of electric driving would be sufficient to ensure its adoption even at a comparatively high price. So far as the first reason is concerned, at the stage at which the undertaking had now arrived, the advantage in cost of production with an individual consumer's steady load over an intermittent load was greatly diminished, because with a total demand of 15,000 H.P., the consumers' loads, however intermittent individually, might be relied upon to a large extent to level themselves out in the aggregate. The second reason, that of meeting the keenest competition with the lowest price, still remained.

There were, however, some disadvantages in the system which became more evident as the number of consumers increased. The maximum demand was supposed to be ascertained by a member of the staff of the electric lighting department, who, however efficient, could not, in the nature of things, be expected to always obtain it with absolute accuracy. Room was left for dispute with consumers as to the amount of the maximum demand, and there was a possibility of pressure being brought to bear to have it understated, with a view to the consumer being charged at a lower price than he should be. A large amount of time was occupied in obtaining and revising the maximum demands, and in calculating the proper charge quarter by quarter. The system was not so easily understood by consumers as one based simply upon the quantity used. It was not practicable at present to abolish the maximum demand system, because a considerable number of consumers were obtaining great benefits from it which they were fairly entitled to, and much dissatisfaction would be caused by an attempt to deprive them of that advantage. It was worth noting that during the 18 years running of the undertaking no alteration of prices had ever been made which caused a single consumer to pay a higher rate than before.

The object should be, therefore, not to abolish immediately the maximum demand system, but to supersede it partially by giving greater advantages to the majority of the consumers in another way, and ultimately to give everyone a power supply at a figure not exceeding the lowest price now charged under the maximum demand system (0·9d. per unit). The effect of the proposed amendments in the scale of charges was therefore :—(*a*) To reduce the maximum price from 1¾d. to 1½d. per unit. There were over 50 towns in which the maximum price for power was less than 1¾d. per unit, and it was advisable to remove the handicap upon the small power users of Leeds. (*b*) To give concessions, based solely upon the quantity used, to all consumers using 3,000 units or upwards (say, £17 worth) in a quarter. (*c*) To reduce the minimum price from 0·8d. per unit to 0·75d. per unit, less 5 per cent. discount, and to bring the minimum price within the reach of a somewhat larger number of consumers. It was estimated that the result of these concessions would be a loss of revenue amounting to £2,350 per annum, based upon the present output, and without allowing for the countervailing gain by the resulting increase of business.

In order to obtain an extended demand for current for heating purposes it appeared necessary to reduce the price from 1½d. to 1d. per unit. The present revenue from that source is about £450 per annum, and, therefore, the reduction would represent £150 per annum. The estimate of income and expenditure for the ensuing year allowed for the proposed reductions in prices. It was suggested, however, that they should be brought into force on July 1 next.

The revised scale of charges is as follows :—

Power.—The price of energy used in motors (when the installation is not less than ¼ H.P.) is based upon the number of units consumed per kilowatt of the consumer's maximum load. In any quarter when units consumed are less than 450 per kilowatt, 1½d. per unit, less than 600 units 1¼d., less than 720 units 1⅛d., less than 850 units 1d., less than 1,000 units 0·95d., when units consumed per kilowatt are 1,000 or upwards 0·9d.

Provided that in any quarter when the units consumed are 3,000 or upwards the price shall not exceed 1⅜d. per unit, 5,000 1¼d., 10,000 1⅛d., 20,000 1d., 50,000 0·95d., 100,000 to 149,999 units 0·9d., 150,000 to 199,999 units 0·85d., 200,000 to 399,999 units 0·8d., and 400,000 units or upwards 0·75d. per unit.

For ascertaining the price to be charged users of motive power are asked to state their maximum load, but in case of any difference of opinion on the point, the decision of the manager of the department shall be final.

Heating.—Electricity used for cooking or other heating purposes is supplied at 1d. per unit. A discount of 5 per cent. is allowed upon all accounts for payment within one month of rendering.

LEGAL INTELLIGENCE.

London Electric Supply Corpn. (Ltd.) v. Westminster Electric Supply Corpn. (Ltd.)

Mr. Justice Joyce delivered his reserved judgment in this case on Saturday. The facts were reported in THE ELECTRICIAN for March 3 and 10.

In delivering his judgment, his Lordship recapitulated the circumstances under which plaintiffs entered into an agreement with the defendant company on May 4, 1910. It was an elaborate and complicated document, well considered and carefully prepared, each party no doubt having the best legal advice and assistance. Speaking broadly, the effect of it was that the defendant company took over, for its own benefit, the working of plaintiff company's undertaking in the Westminster area, so far as the law allowed, until it should be purchased by the local authority, the consideration being a fixed annual payment of about £22,000 per annum, and certain other arrangements; with reference to various incidental matters, and, in particular, in reference to the proceeds of sale upon purchase by the authority, the arrangement as to that was, in substance, that upon the purchase by the local authority plaintiff company should receive the price of their undertaking notwithstanding the agreement for working by defendant company, and if the price were less than £100,000 defendant company were to pay plaintiff company the difference. It was provided by clause 11 of the agreement that defendant company should fulfil all conditions and requirements in respect to the supply of electrical energy to which the plaintiff company was or might become subject within the Westminster area, and should indemnify plaintiff company in respect of all claims against plaintiff company by reason of any default in such supply, provided that such default did not arise from the default or neglect of plaintiff company. Upon the sanction of the agreement by the Board of Trade plaintiff company handed over to defendant company and the latter assumed the management and working of plaintiff company's undertaking in the Westminster area. Plaintiff company first asked for an injunction to restrain defendant company from soliciting or attempting to induce any consumer in the Westminter area, who now took, or might hereafter take plaintiff company's alternating current, to cease to take same and in lieu thereof to take defendant company's continuous current. The claim to the injunction was based upon the contention that defendant company (as managers of plaintiff company's undertaking) were in a fiduciary position to them and bound even to prefer the plaintiff company's interest to their own. Certain authorities were quoted in support, but in his Lordship's opinion the claim was founded upon an entire misconception of the relation between the two companies. Defendant company were entitled (subject to their statutory obligations, and to clause 11 and fulfilling the explicit stipulations of the agreement) to work plaintiff company's undertaking for their own benefit. The defendant company, broadly speaking, purchased so far as the law would allow the right to work and take the profits for themselves of plaintiff company's undertaking in the Westminster area, managing it in their own interest entirely. That was in substance the object and intention of the whole arrangement. In regard to the contention that defendant company was precluded by the agreement from doing anything directly or indirectly to reduce or diminish the requirements of plaintiff company's consumers for alternating current, his lordship came to the conclusion that that contention could not be supported, and held, as a matter of fact, that defendant company had not really done anything intended or calculated to induce any consumers in the area, who at the date of the agreement took plaintiff company's alternating current, to cease or discontinue doing so, or to induce any such consumers to take defendant company's continuous current instead. He also held that plaintiffs had not established their claim for a declaration that, according to the true construction of the agreement, defendant company, not as between themselves and the public, but as between the two companies, was bound to supply electric energy by means of plaintiff company's alternating current to any consumer in the Westminster area who might apply to plaintiff company for a supply of electrical energy by means of alternating current. The action was accordingly dismissed with costs.

National Telephone Co. and the Postmaster-General.

On Friday last the Railway and Canal Commissioners (Mr. Justice A. T. Lawrence, the Hon. A. E. Gathorne-Hardy and Sir J. Woodhouse) heard an appeal by the National Telephone Co. from an order of the Registrar granting the Postmaster-General leave to administer interrogatories with reference to land, plant and buildings in various parts of the country which the company alleged that the Postmaster-General had to purchase at the end of the present year, when (under agreement) he acquired the whole of the undertaking of the company.

Mr. E. MORTEN, K.C. (with him Mr. Gaine), in support of the appeal said the Postmaster-General had entered into an agreement to acquire the undertaking of the National Co. at the end of 1911, and under that agreement the Postmaster-General had the right to object to purchase land, plant and buildings which he considered unsuitable for the telephone business. The Postmaster-General had given notices that he objected to purchase certain land, plant and buildings in different parts of the country, on the ground that they would not be suitable for the telephone business at Dec. 31 next. A dispute had arisen between the parties, and the court had to decide the matters in dispute, as arbitrators. The company had filed an application alleging that the notices of the Postmaster-General were not specific, and, consequently, not good. The case for the

Digitized by Google

contrary was that the Postmaster-General was seeking to interpret the word "immaterial" as meaning "unnecessary." The Registrar had given the Postmaster-General liberty to administer certain interrogatories to the company with reference to certain of these matters. Those interrogatories placed an enormous burden on the company for no good reason, and asked for information which was irrelevant and immaterial to the present application, but which would be material when the Commissioners came to value the property of the company. At present there were 200 men at work preparing an inventory of the property to be valued by the Postmaster-General. They had been at work for months, and not more than 20 per cent. of the work had been done. It was estimated that it would take 15 months to complete the inventory.

Mr. Justice LAWRENCE: Your contention is that for the purpose of proceedings at arbitration the information asked for would be superfluous?

Mr. MORTON: Yes. But he would be prepared before the arbitration proceedings to give the Postmaster-General a list of the points which the company proposed to put in evidence in support of their contention that the valuations were bad.

Mr. Justice LAWRENCE said the Court was of opinion that the company should not be called upon to answer the interrogatories. If during the proceedings it was shown that further information ought to be supplied the company to the Postmaster-General an order to that effect would be made.

The appeal was accordingly allowed.

Re Connolly Bros. (Ltd.); Wood v. Connolly Bros. and Others.

On Tuesday last week the Court of Appeal (the Master of the Rolls and Lords Justices Moulton and Buckley) dismissed the appeal of (Sir) Mr. J. J. O'Reilly) from an order of Mr. Justice Parker restraining appellant from proceeding in the County Palatine Court of Lancaster to the appointment of a receiver over certain mortgaged property of the company. On Feb. 17 last plaintiffs (holders of a £20,000 debentures) issued a writ to enforce their security, and Mr. Justice Parker appointed a receiver and manager. Appellant, who holds a first equitable charge over a plot of land in Manchester acquired by the company, obtained the appointment of a receiver in the County Palatine Court, both parties being desirous of enforcing their security. An application was made to restrain Mr. O'Reilly from continuing his action in the County Palatine Court, and Mr. Justice Parker made the order restraining Mr. O'Reilly from proceeding with his action, but said that the debenture holders' receiver desired possession of the plot of land he could pay the appellant rent for it, and if he did not desire possession he would be at liberty to make an income from it in some other way.

After the conclusion of arguments their lordships upheld the decision of Mr. Justice Parker and dismissed the appeal, but said taht there was nothing in the order of the court which would prevent appellant from making an application (if necessary) to discharge the receiver.

Fry v. Wilson.

On Friday Mr. Draper, on behalf of the defendant (Mr. W. H. Wilson), moved to commit for contempt of court plaintiff (Mr. J. T. Fry) on the ground that plaintiff had grossly interfered with the receiver appointed on the application of defendant to take charge of partnership assets.

Counsel stated that the parties carried on business as electrical engineers at Bromley, Kent, and plaintiff lived at the back of the business premises. The receiver appointed by the court (Mr. Hicks) informed plaintiff that he was not to go into the shop, but afterwards he had reason to believe that papers, &c., belonging to the business were being tampered with. He decided to put a barrier between the shop and plaintiff's living apartments. Plaintiff and plaintiff's son, however, claim the right to go. This defendant submitted was a gross interference with the receiver.

Plaintiff (through counsel) expressed regret for the damage, but denied that he in any way interfered with the papers, &c., of the business or attempted to obstruct the receiver.

Mr. Justice SWINFEN EADY said there was no evidence to show that plaintiff had tampered with the papers, &c., but he was satisfied that plaintiff's action in regard to the barrier did amount to gross interference with the receiver in his duties, and he made an order committing Fry to prison.

Trade Secrets.

On Monday the Court of Appeal (the Lord Chief Justice, Mr. Justice Phillimore and Mr. Justice Coleridge) heard the appeal of F. Kurt Huessener and Schroeder, who were sentenced at the recent Newcastle Assizes to four months' imprisonment respectively for corruptly giving presents of the Thermal Synd. (Wallsend) by offering them inducements for obtaining information from them about the prosecuting company's works.

Mr. Bigham (for appellants) said the Thermal Synd. were manufacturers of silica and their only competitors in England were Silica Ware Co., the managing director of which Mr. Huessener was managing director. The charge against appellants was that they met two servants of the Thermal Synd. at Newcastle, and, by giving them small sums of money and offering them employment at the company's works at Zurich, endeavoured to extract from them information regarding the manufacture of certain kinds of silica. He contended that there was not sufficient evidence to prove that the sums offered were bribes. The offers of employment were bona-fide, and, having regard to the fact that even if defendants had gained any information, they had gained it prematurely only. If they had underhandedly enticed the Thermal Synd.'s employés away and got secrets out of them after having employed them, that would not be illegal.

The LORD CHIEF JUSTICE said it was true that the sums offered to the men were small, but, together with the suggested offer of employment, they were tempting. He thought the case was one for the jury. Such offences as those were very difficult to prove, and only a small number of the offences were discovered. In those circumstances the judge was bound to deal with the matter severely, for it may have been that that was the first of a series of attempts to get trained men with secrets away from a rival manufactory by bribery. The appeal was accordingly dismissed.

Arc Lamps (Ltd.)—On Tuesday Mr. Justice Swinfen Eady had before him the petition of Siemens Bros. Dynamo Works (Ltd.) for the compulsory winding up of this company. Mr. Edwards appeared, and said he was instructed to withdraw the petition, having received no notice of support. The petition was, therefore, dismissed, without costs.

PARLIAMENTARY INTELLIGENCE.

NORTHAMPTON CORPORATION BILL.

The consideration of this bill has been continued by a Select Committee of the House of Commons.

Mr. STANLEY CLEGG, city electrical engineer and tramways manager, Lincoln, said electric tramcars were run satisfactorily over a level crossing at Lincoln, where both the road and railway traffic was greater than in the Northampton case.

Mr. LLOYD, K.C., said he had witnesses who could give similar evidence with regard to Birmingham, Gloucester and Glasgow, but the Chairman did not think it necessary to call them.

Mr. ROBT. TURNBULL, superintendent of the line (L. & N.W. Railway), said the company strongly objected to the proposed crossing. The number of trains crossing it was 32 per day. Throughout their system of 2,000 miles there was only one tramway crossing the line on the level—viz., at Manington. The railway traffic would probably be increased, as it was in contemplation to bring the Midland trains into Northampton N.W. station.

Sir CHARLES OWENS, general manager of the L. & S.W. Railway, said he viewed the level crossing proposal with grave apprehension.

Mr. TALBOT, K.C., having addressed the Committee on behalf of the L. & N.W. Railway Co.,

The CHAIRMAN said the Committee regretted that the parties had not been able to come to an arrangement, because they thought the erection of a bridge would be the most satisfactory solution. Failing that, they decided to give the Corporation the right to lay this tramway down, because they thought in that case it could be done without any injury.

The Committee subsequently passed the proposals with regard to other tramway extensions, and also the provision for running rail-less trolley vehicles, but amended the latter so that the use of such vehicles should not commence before Jan. 1913.

Mr. GOTTSCHALK (tramways manager at Northampton) said they would not go on with the last-mentioned proposal if the experiments with the rail-less trolley cars at Leeds and Bradford were unsuccessful.

Nottinghamshire & Derbyshire Tramways Bill.—Last week the Select Committee of the House of Commons dealing with unopposed bills passed the preamble of this Bill. The Parliamentary agent, Mr. Bell, explained that by arrangement with Nottingham Corporation and other bodies, they were now able to produce something like a complete scheme, and all opposition had been met. Nottingham Corporation was to construct the portion of the lines within the city, and the company was to work it.

Liverpool Overhead Railway Bill.—The House of Commons Committee on unopposed Bills has passed the preamble of this Bill, which gives the company further capital powers.

Croydon and Southern District Rail-less Traction Bill.—The promoters have intimated that they will not proceed with this bill.

National Telephone Co's Employes.—In the House of Commons on Tuesday the Postmaster-General (Mr. H. Samuel) stated, in reply to a question, that the employés of the National Telephone Co., on their transfer to the Post Office, would enjoy the advantages of the rank and grade to which they were admitted, and, in so far as their salaries had not been raised on account of duties connected with the transfer or in any way abnormally since Jan. 1, 1909, he thought he could say that the rates of pay would not be less—and in many cases would be greater—than had been paid by the company.

Private Bill Legislation.—A Bill is being promoted to authorise the transfer of the powers of the Kent Electric Power Co. in regard to a portion of their area to a company to be incorporated (or any company or persons to be named in the Bill), and to authorise extensions of the company's area from time to time, the acquisition of lands, the execution of works, the letting on hire of machinery, plant, apparatus, &c.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Ashton-under-Lyne.—Owing to the increasing demand for electrical energy for power and lighting, the Council are recommended to expend £30,000 on various extensions of generating plant and supply mains.

Barmouth.—At a meeting of tradesmen last week, presided over by the Reb. G. Davies, a sub-committee was appointed to report upon an electricity scheme submitted by Mr. C. Balbiani, electrical engineer.

Barnsley.—The Corporation have decided to apply for sanction to a loan of £16,100 for extensions of the electricity supply undertaking.

The Chairman of the Electric Lighting Committee (Ald. Brady) stated at the Council meeting on Tuesday that Mr. J. F. C. Snell had reported that there was great scope in the borough for an increased output of electricity, and that the electricity department was financially sound. Last year the revenue increased by £916.

Bradford.—At a meeting of the Tramways Committee on Monday the manager (Mr. C. J. Spencer) reported on the effect of the alterations in wages and service conditions of employés sanctioned by the Council in December.

At the time it was suggested that many employés could make themselves worth considerable more pay by better attention to work, and that a scheme of increased payment and holidays in which such employés were discriminated from others would tend to higher efficiency. Mr. Spencer gives tables showing number of advances in wages on March 31, compared with Jan. 17, were: Drivers, 168 granted ½d. an hour increase, against 128; 74 granted ¼d., against 49; 15 applications refused or deferred, against 66. Conductors, 42 granted ½d., against 28; 59 granted ¼d., against 41; 33 deferred or refused, against 62. The wages bill for the quarter was about £760 higher than the average, and as the various increases came into operation that figure would advance, so that the original estimate of extra cost (£4,561) would probably be slightly increased.

The summarised results of the operation of the scheme during the quarter were put at: 52·17 per cent. decrease in number of irregularities of drivers and conductors, 14·29 per cent. decrease in accidents, 39 per cent. reduction in number of cars taken out of service for defects, and 6·2 per cent. reduction in consumption of current.

The Committee inspected a new brake, the invention of the manager, expressed their approval of it, and decided to ask the Board of Trade to examine it.

At the last meeting of the Electricity Committee the city electrical engineer (Mr. T. Roles) reported in favour of installing a third 3,000 kw. turbo-generator, as an addition to the two already installed, together with switchgear, &c., at an estimated cost of £20,000. Consideration of the matter was adjourned.

It is estimated that the output of electricity in the year which has just closed will have reached 20,000,000 units for the first time in the history of the department, or about 2,000,000 units in excess of last year.

Bristol.—The salary of the city electrical engineer (Mr. H. Faraday Proctor, M.I.C.E., M.I.E.E.) is to be increased from £700 to £750 per annum and subsequently by two annual increments of £25 to £800 per annum.

Burnley.—The following reductions have been made in the charges for electricity, as from the 1st inst.

For traction, from 1·25d. to 1·2d. per unit; lighting from 3¼d. flat rate to 3d., less 5 per cent. discount for cash within 21 days; Coronation illuminations 1½d. per unit.

Carnarvon.—The Castle is to have the electric light installed in time for the investiture of the Prince of Wales.

Coronation Illumination.—*Westminster* City Council will expend about £1,000 on the illumination of Constitution Hill and St. James's-street.—*Stepney* (London) Council have decided to spend £300 on the illumination of public buildings.—*Burnley* Electricity Committee have decided to supply consumers with current for Coronation illumination purposes at 1½d. per unit.—*Leeds* Tramways and Electricity Committee are arranging for the running of illuminated cars in the latter half of Coronation Week. There will also be special illumination, including a searchlight at the Town Hall.—*Deptford* (London) General Purposes Committee recommend the expenditure of £150 on the illumination and decoration of the Town Hall.

Eccles.—The Council have received sanction to a loan of £360 for the extension of a h.t. feeder and £500 for the provision of electric motors.

Electricity in Mining.—At the meeting of the Ooregum Gold Mining Co. (Ltd.) on Tuesday the chairman (Mr. Malcolm Low) said that the supply of electrical energy from the Cauvery River was so satisfactory that it was highly desirable that it should be extended. Electric power was well suited for the purposes of the mine, and it would mean a further decrease in costs if further supplies could be arranged.

Negotiations had been in hand for some considerable time, and as a result of interviews which he had with officials of the Mysore State, terms were agreed upon which would be acceptable to the companies. The completion of the scheme now awaited the concurrence of the Madras Government, who had certain rights in the Cauvery River. The electrical work on the field was carried on through a department representing all the companies, and was under the supervision of a capable head in Mr. F. M. Nicholl.

Fatality.—An unfortunate fatality occurred in Abington-street, Blackpool, on Monday evening.

A young electrician named George Lewis and another employé of the Corporation were fixing a number of arc lamps near to the new post office when Lewis, who was coupling up the cables in the ground at the foot of one of the posts, received a fatal shock from a "live" electric cable, which was carrying current at 2,000 volts. Deceased had been asked shortly before the accident to put on rubber gloves for protection, but replied that he would be finished in five minutes, and the current could then be switched on.

Glasgow.—The tramways manager (Mr. Jas. Dalrymple) has reported to the Tramways Committee that the experiment of issuing two-stage tickets has considerably reduced the number of penny fares; but, on the other hand, a great many passengers who formerly took only half-penny tickets are now using two-stage tickets.

The tickets also appear to have had the effect of increasing the number of travellers for short distances. The result is that the increase in revenue from the increased traffic has more than met any reduction in revenue caused by the falling off in the number of penny passengers. Consequently the two-stage tickets will now become permanent.

Halifax.—Electric current for heating is to be supplied at power rates.

Hornsey.—Another boiler and two coal bunkers will have to be provided at a cost of £3,500 to meet next winter's demand for electrical energy. Further extensions of buildings may also be required, and the estimated cost of these is £5,450. Application is to be made to the L.G. Board for sanction to borrow £9,600.

Hulton Colliery Disaster.—The representatives of the Miners' Federation (Messrs. R. Smillie and W. Straker), who were present at the recent Government inquiry into the circumstances attending the disastrous explosion at the Pretoria Pit in December, have prepared their report on the matter, which will be submitted to the next meeting of the Executive Council of the Federation.

The report declares that the miners' representatives are satisfied that the fire originated at No. 1 heading, North Plodder seam, and was due to an electric spark from the conveying switch coming in contact with gas or gas and coal dust. The management of the mine is criticised, and, in regard to the system of ventilation, it is pointed out that under the Coal Mines Regulation Act all mechanical ventilating appliances are required to be in such a position as will make it impossible for them to be destroyed by a serious explosion. In the case of the Pretoria Pit, it is alleged that the ventilation was not in accordance with this regulation, being obtained from underground high-speed electric fans placed in such position as to ensure their being amongst the first things to be destroyed by a serious explosion.

The report condemns the use of electricity in the pit under the circumstances, alleging that electrically-driven machinery was used in parts of the mine where there was an abnormal proportion of gas. The report calls for more stringent regulations respecting the use of electricity and their more general enforcement. The need for a large increase of the inspectorial staff is also urged.

Inquest.—An inquest was held on Saturday into the death of Mr. Wm. Middleton, station superintendent of the Newcastle & District Electric Lighting Co., who died at a private hospital in Newcastle

Digitized by Google

...e result of burns received while examining a switchboard on the ...ernoon of 16th inst.

...evidence showed that deceased was investigating a fault behind ... switchboard when a report was heard. A witness named MURRAY said ... and Mr. Middleton's coat and waistcoat on fire. He thought a ... had occurred.

Mr. J. LISTER, electrical superintendent of the Newcastle & District ..., said the switchboard would have been safer with a slate partition ... the terminals, and that was the practice now usually followed. ... jury returned a verdict of accidental death, and added that the ...board was dangerous and a partition should be put in.

Limerick.—In the estimates of the Electric Lighting Committee for ... coming year, provision is made for a deficit of £1,662. 9s. 10d. on ... working.

Lincoln.—At the last meeting of the City Council Mr. W. S. White, ... of the Electricity Works Committee, in moving the adop... the minutes of the Committee, announced that £2,000 would ... from the electricity profits to the reduction of rates. In ... £1,000 was voted for the same purpose, so that £3,000 of the ... of the department had gone in this relief.

... Committee, Mr. WHITE said, they would have liked to ... that to their depreciation account. They had sunk about ... electricity supply and £45,000 in the tramways undertaking. ... fund now stood at about £7,500. They were very anxious ... as low as possible, and for that reason the Committee ... vote the £2,000 to the rates.

London County Council.—On Tuesday the Finance Committee ... that the net debt attributable to revenue-producing under... over 50 per cent. of the total, and showed an increase ... for the previous year of £1,374,909. On the tram... London County Council) the debt was £8,899,099, and on ... lighting (metropolitan borough councils) £5,468,409. The ... important revenue-producing undertakings (water and ... had not so far necessitated a charge on the rates. They expect to be in a position too report after ...

Manchester Tramway Workers' Grievances.—Sir D. Harrel, who ... arbitrator in the differences between Manchester Corpora... their tramway employés, sat on Monday at the Town Hall, ... to hear the parties.

Mr. T. Jackson, general secretary of the Tramway & Vehicle ... Association, claimed for the men an eight-hour working day; ... Corporation's case was stated by the chairman (Ald. Bowes) ... and manager (Mr. McElroy).

Marylebone (London).—Mr. A. Hugh Seabrook estimates that ... will be required for short extensions of distributors during ... next 12 months.

Nelson.—Burnley's offer for renting the Nelson section of the ... has been accepted by Nelson Council. The rent is £692 ... annum, and electricity is to be supplied by Nelson at 2d. per ... Nelson Corporation will maintain the track in consideration ... annual payment of £150, and Burnley will maintain the over... plant.

Union Broad.—For some time the Council have been in negotia... with the local electricity company, Lowestoft Corporation and ... Anglian Ice Co. in regard to a supply of electricity, and the ... have now adopted a recommendation of their Electric Light... Committee to accept the offer of the Ice Co., subject to an agree... to be entered into, and upon the necessary borrowing powers ... obtained. Sanction is to be obtained for borrowing not ex... £4,000, to enable the Council to carry out their powers under ... Provisional Order.

Prestwood.—Somerset County Council have decided not to object ... application for a provisional electric lighting order provided ... parties agree that the cables should be underground in ... streets in Walton Park, that the streets in which mains are ... laid within two years include a length of one mile in the village ... half a mile in the village of Long Ashton, and half a mile in ... Leigh Woods.

Presentations.—The Chelmsford staff of Crompton & Co. have ... a marble clock and ornaments to Mr. T. L. Bowles, on his ... On retiring after 38 years' service at Woolwich with Messrs. Siemens Bros. & Co., Mr. G. Forrest has been presented by the Woolwich and London staffs and the Woolwich employés with a gold watch and chain, a chiming clock, two arm chairs and a case of pipes.

Scarborough.—The electric tramway service was re-commenced on Monday.

The Corporation have given notice to the local electric supply company that on the termination of the existing agreement they will pay for electrical energy supplied to the Corporation depot by meter.

South Shields.—On Monday a scheme of extensions at the electricity works, estimated to cost about £11,000, has been drawn up by the borough electrical engineer, Mr. J. H. Cawthra. The scheme, which has been approved by the consulting engineer (Mr. J. F. C. Snell) provides for the erection of a 1,500 kw. turbine direct coupled to a 1,000 kw. d.c. generator, and an 1,100 kw. alternator with pipework, switchboard, &c. The L.G. Board will be asked to grant a loan of £7,580, the balance to be provided out of the reserve fund.

Swansea.—The Electricity Committee recommend the Council to proceed with the proposed extension of the plant at the electricity supply works. The slaughter house and cattle market are to be wired.

Telephone Authority.—Mr. H. Laws Webb returns to the subject of a central telephone authority to organise, conduct and develop the telephone service in this country in a communication to the "Times" of the 8th, where the views of Mr. T. N. Vail, president of the American Telephone and Telegraph Co., (as expressed in a report regarding that company's operations for the year 1910), are set out. In this report it is stated that the "Bell" telephone system of the United States increased during 1910 by 740,027 stations, bringing the total to 5,882,710, and Mr. Webb points out that the total number of stations in this country does not yet nearly represent this increase made in the United States during 1910, that is to say, our total is 644,000 stations after 31 year's public use of the telephone. Mr. Webb points out that, so far, his proposal for a Central Telephone Authority has not received a single unfavourable comment.

Watford.—The Finance Committee, having again considered the comparative cost of street lighing by electricity and gas, unanimously recommend that no change be made.

At the last meeting of Council, when the recommendation was adopted, the chairman of the Electricity Committee (Mr. Goodrich) said the department was paying its way, and he thought he could forecast that the financial year which had just closed would show a profit of about £500. In 1906 the Council were paying £4,174 for 16,000 c.p. for street lighting, whereas, before next winter, they would be having 70,000 c.p. for the same sum.

Wimbledon.—A sub-committee, appointed to consider alternative routes for laying cables to the Maldens and Coombe, have submitted three alternative schemes, the cost being respectively £3,719, £3,241 and £7,459.

A draft agreement has been approved as to a supply of energy to the sewage pumping station and works of Merton Council in West Barnes-lane.

Wireless Telegraph Notes.—The Netherlands East Indies have adhered to the International Wireless Telegraph Convention of Berlin.

The Société Française Radio-Electrique, 128, Rue de la Boétie, Paris, state ("The Times," 12th inst.) that the emission from the Eiffel Tower by means of their singing sparks has been clearly heard by the Glace Bay station in Canada, a distance of over 3,000 miles, with an expenditure of energy at the Eiffel Tower of only 13 H.P. They claim that this result is of great importance, because up to the present 150 H.P. has been required to communicate to such a distance, and that it shows the improvement which has been effected. They state, further, that the receiving conditions were unfavourable, in that while the wave-length employed at the Eiffel Tower was just over 2,000 metres, the Glace Bay station received the messages with a wave-length of 4,000 metres.

Woodbridge.—At the last meeting of the Council representatives of Messrs. Foote & Milne attended to give particulars of the proposed electricity scheme for the district. After discussion the Council appointed an Electricity Committee to go into the details of the subject and to report to the Council.

Worthing.—It is reported that, instead of an anticipated deficit of £124 on the past year's working of the electricity undertaking, there was a net profit of about £7.

York.—In moving the adoption of the minutes of the Electricity Committee at the City Council meeting on Monday the chairman

Digitized by Google

(Ald. Meyer) said they were of opinion that a reserve fund should be formed as soon as possible.

Ald. MEYER also said the amount of the sinking fund on their borrowed capital was £5,326, while the interest only came to £4,500. They were bound by the regulations of the L.G. Board, and they not only had to renew their plant out of revenue, but had also to pay the whole of the capital cost of the plant in a certain number of years. It was the last regulation which made it necessary to form a renewal fund.

Social.—The employés of Messrs. Elliott Bros., Century Works, Lewisham, S.E., held a successful social evening at the Blackheath Concert Hall on April 1.

The hall was filled to its utmost capacity, a number of local residents kindly giving their services for the entertainment, which was entirely to the liking of the audience. The music rendered by the Century Works Orchestra added to the enjoyment of the evening.

Dinner.—The electrical engineer ex-apprentices and apprentice at Devonport have formed themselves into an association, and the inaugural dinner was held at Plymouth on Saturday. Mr. Z. H. Kingdon presided, and among those present were Messrs. E. E. Benham, G. R. Battle, J. C. Uglow and W. J. Wotton.

In addition to a large gathering of ex-apprentices and apprentices of the electrical engineer's department, representatives of similar associations in other departments, and Mr. Maker, chairman of the Electrical Fitters' Association, attended.

COLONIAL AND FOREIGN NOTES.

Angola (West Africa).—It is proposed to use water power at Katanga for the generation of electrical energy for haulage and lighting in the Star of the Congo Mine.

Austria-Hungary.—The Severoceske Elektrárny Spolecnost has been formed at Leitmeritz with a capital of £62,500 to promote electricity supply undertakings.

The Elektrizitätswerk Semmering Gesellschaft has obtained a concession for the construction of electric tramways of Semmering.

Batavia (East Indies).—A group of Chinese capitalists (represented by a European) have applied to the Netherlands East Indies Government for a concession for the construction and working of electric tramways in Batavia.

Chinese Telegraphs.—The important announcement is made that the Eastern Extension, Australasia & China Telegraph Co. and the Great Northern Telegraph Co. have arranged to provide the Chinese Telegraph Administration with the sum of £500,000 by way of advance on the receipts which will become due to the Chinese Administration on the foreign traffic during the next 18 years. The interest payable to the Companies is 5 per cent. It is a stipulation of the advance that the money shall be used only for the development of the Chinese telegraphs and telephones. The arrangement is regarded in financial and telegraph circles as a departure in the best interests of all parties concerned.

Russia.—Kharkov Municipality have applied to the Ministry of the Interior for authority to borrow £654,000 for the extension of their electricity works, construction of tramways, water works, &c.

South Africa.—The "British and South African Export Gazette" states that there is likely to be an increased demand for electric lighting appliances in Pietermaritzburg, as the Municipality has decided to assist householders in making installations.

Electricity supply works have been equipped at Ceres (Cape Province) and water power is used for driving the generating plant.

The estimates of the Finance Committee of Johannesburg Corporation for the five years 1911-1915 include £289,680 for electricity supply and £298,236 for electric tramway purposes.

Turin International Exhibition.—The British section of the Turin Exhibition is self-contained, and British-made machinery need not be looked for in the International Machinery Hall, for examples of the most recent developments in electrical plant, agricultural and textile machinery, gas and oil engines and machine tools will be found in a hall which forms, facing the river, the left wing of the British Pavilion.

Leaving the machinery hall a visitor will first pass through the land transport court, which contains fine examples of the advance made of late years by Great Britain in the manufacture of motor cars. This court contains 35 cars. He will next reach the court of chemical and scientific industries, where everything is to be shown, as far as possible, under actual working conditions. Two completely-equipped laboratories are shown, and mark the inauguration of a novel and eminently practical method of exhibition. So far as the pottery industry is concerned, Great Britain has recently taken a decided lead. In one or two cases, after years of patient experimental research, her potters claim to have re-discovered the long-lost secrets of the art of the ancients in this respect, and what is shown may, therefore, be regarded as being among the most valuable contributions to the section.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

FULHAM (London) Borough Council invite tenders for the supply, delivery and erection of a 1,500 kw. turbo-alternator with condensing plant. Specification plan and form of tender from the borough electrical engineer, Mr. A. J. Fuller. Tenders by noon of Wednesday, April 26 to the town clerk, Mr. J. Percy Shuter, Town Hall, Fulham, S.W. See an advertisement.

ST. PANCRAS (London) Borough Council invite tenders for three-phase h.t. cable. Copies of specification, conditions of contract and form of tender from the Electricity Department, Offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk, Mr. C. H. F. Barrett, Town Hall, Pancras-road, N.W., by noon Monday May 15. See advertisement.

ST. PANCRAS (London) Council also invite tenders for stoneware ducts. Specification, &c., from the Electricity Department, 57, Pratt-street, N.W. Tenders to the Town Clerk, Mr. C. H. F. Barrett, Town Hall, Pancras-road, N.W., by noon, May 15. See advertisement.

DERBY Corporation invite tenders for supply of inverted rotary converters, e.h.t. cable and switchgear. Specifications and forms of tender from the borough electrical engineer, Mr. T. P. Wilmshurst, 16, Full-street, Derby. See also an advertisement.

Tenders are invited up to May 30 for the supply of one portable petrol-driven desiccating plant to the Postmaster-General's department in Victoria, and up to May 31 for the supply of 7,000 insulators and wire and line material to the Postmaster-General's department in SOUTH AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisements.

Tenders are invited up to May 16 for the supply of 10,000 protectors for use at subscribers' telephone stations to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c., to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are invited for supply of new or second-hand transformers and rotary converters, or motor-generator sets for transforming three-phase 25-cycle 13,200, 2,200 or 550-volt a.c. into 240-300-volt d.c. in output capacities ranging from 100 to 1,000 kw. See an advertisement.

The EGHAM & DISTRICT ELECTRIC LIGHT CO. (LTD.) invite tenders for supply of two high-speed Diesel oil engines, coupled to two 100 kw. single-phase alternators, with direct-coupled exciters, piping, tanks and accessories; one 4-ton overhead traveller and main h.t. switchboard. Specifications, drawings and forms of tender may be seen at,

Digitized by Google

but not obtained from the offices of the company's consulting engineers (Messrs. Handcock & Dykes), 1, Victoria-street, Westminster, S.W., and copies of specifications, &c., may be obtained from the secretary (Mr. H. T. Manwaring), 53, Cannon-street, London, E.C., to whom tenders by noon Monday, April 24.

Tenders are wanted for supply and erection of about 20 high candle-power arcs, four searchlights, about 200 incandescents, &c., and supply of field telephones, for the United Services Tournament camp at Watford. Particulars from Secretary, 76, Victoria-street, London, S.W.

BURY (Lancs.) Corporation invite tenders for supply and fixing of cranes and fittings for the electric lighting of the Chamber Hall power station, together with the provision of certain motor supply circuits. Specifications, &c., from the manager, Mr. S. J. Watson. Tenders to the Town Clerk by noon, April 21.

KETTERING Urban District Council invite tenders for supply, delivery and erection at their electricity generating station of a cooling tower and tank and extension switchboard panels. Copies of specification, &c., from the clerk to the Council, Mr. John Bond, to whom tenders by Wednesday, April 19.

The Electricity Committee of ST. HELENS Corporation invite tenders for supply and erection of a 1,500 kw. high-pressure turbo-alternator, with condensing plant and switchgear. Drawings, specifications and forms of tender from the borough electrical engineer, Mr. E. M. Hollingsworth, Croppers-hill, St. Helens. Tenders to the Chairman of the Electricity Committee, Town Hall, St. Helens, by noon Thursday, April 20.

GLASGOW Corporation invite tenders for supply and erection of a steam turbo-alternator, with condensing plant for Pinkston generating station. Tenders to town clerk, Mr. A. W. Myles, City-chambers, Glasgow, by 10 a.m. April 24.

HORNSEY Town Council require tenders by 4 p.m. April 24 for supply and erection of flame arc lamps. Forms of tender, &c., from the Borough Electrical Engineer.

WALTHAMSTOW Council want tenders by 5 p.m. April 28 for a cooling tower and switchboard extension (two panels). Specifications &c., from Mr. G. R. Spurr, Electricity Works, Walthamstow.

GLASGOW Parish Council and Lunacy Board want tenders by 10 a.m. April 24 for 12 months' supply of electric lamps and fittings. Forms, &c., from Mr. J. R. Motion, 266, George-street, Glasgow.

DUDLEY Corporation require tenders by noon April 19 for 12 months' supply of service cables and accessories, i.r. cables, electrical fittings, carbons, carbon brushes, carbon filament lamps, &c.

TONBRIDGE Council want tenders by noon April 21 for electric pumping plant and about 1,600 yds. of electric mains in connection with sewerage works.

DUBLIN Public Libraries Committee want tenders by noon April 26 for the electric lighting of the new portion of Charleville Mall Public Library. Specification, &c., from the City Electrical Engineer.

SWANSEA Corporation require tenders by noon April 24 for the supply of 2,000 brass condenser tubes for the electricity department. Forms of tender, &c., from the Borough Electrical Engineer.

LEYTON Corporation want tenders by 7 p.m. April 24 for supply and erection of turbine generators, condensing plant, and cooling tower. Specifications, &c., from the Borough Electrical Engineer.

HEYWOOD Electricity Committee require tenders by noon April 19 for iron stores. Particulars from the Electricity Works.

Tenders are invited by the City of MELBOURNE for supply of 120 single-phase 200 volt a.c. watt-hour meters. Copies of specification and forms of tender from the agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter Square-buildings, London, E.C., where tenders are to be sent by noon, April 21.

Tenders are also invited by the MELBOURNE City Council for the supply, delivery and erection of a battery of accumulators with boosters and switchboards. The battery is to be capable of daily maintaining a normal capacity of 4,000 amperes for one hour, during which discharge the voltage of each cell shall not be lower than 1·7, the number of cells to be sufficient to maintain a total voltage across the whole battery of 475 volts at any time during discharge at the specified rate. Tenders are also invited for three years' maintenance. Tender forms, &c., from Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by noon May 8.

Tenders are invited up to April 25 for supply of 175 miles of lead-sheathed cable (lead covered, paper insulated) and 717,000 paper insulators, and up to June 14 for supply of a branching multiple electric lamp signalling switchboard at Ballarat, to the Postmaster-General's Department in VICTORIA; and up to June 14 for supply of a C.B. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA. Tender forms, &c., from 72, Victoria-street, London, S.W.

Tenders will be received until 11 a.m. May 1 by Mr. M. Peterson, Board of Control, WINNIPEG, Canada, for supply of ornamental lighting standards. Specifications, &c., from the City Electrician, or may be seen at 73, Basinghall-street, London, E.C.

The Norwegian State Railway Department, Statsbaneme, CHRISTIANIA, require tenders by April 21 for supply of telegraph material, including g.i. wire, sal ammoniac, insulators, carbon plates, insulated copper cable and wire. Specifications (in Norwegian) can be seen at 73, Basinghall-street, London, E.C.

Tenders will be received at the Burgermeisteramt, VARNA (Bulgaria), on April 19 for erection and equipment of electricity works at Varna. Conditions (in French) at 73, Basinghall-street, London, E.C.

Tenders will be received at the Tiefbauamt, FRANKFORT-ON-MAIN, on April 23 for supply of 15 electric capstans.

The Turkish Ministry of Public Works, Constantinople, invite tenders until 2 p.m. June 14 (June 1 O.S.) for a concession for the supply of electrical energy for tramway and other purposes in JERUSALEM and its suburbs. Local representation necessary.

The date for receiving tenders for concessions for construction and working electric tramways in ADRIANOPLE and ADANA (Turkey) has been postponed until May 2. Local representation necessary.

TENDERS RECEIVED AND ACCEPTED.

London County Council have accepted the following tenders for supply of tramway parts, equipment, &c., for 12 months ending April, 1912:—

Dyer & Young, motor and generator spares, £265. 10s.; Brecknell, Munro & Rogers, switchgear spares, £101. 13s. 10d.; Dyer & Young, contact fingers, &c., £206. 3s. 6d.; E. Showell & Sons, ditto, £273. 5s. 5d.; M. Mole & Son, pressed brass and steel articles, £161; Sloan Electrical Co., motor and generator brushes, £53. 7s. 3d.; Morgan Crucible Co., ditto, £387; Liverpool Electric Cable Co., electric cable, fuse wire, &c., £980. 18s.; London Electric Wire Co. & Smiths, ditto, £676. 10s.; Midland Electric Wire Co., ditto, £599. 2s.; British Insulated & Helsby Cables, ditto, from £2,848. 10s. to £3,230. 10s.; Western Electric Co., h. and l.t. cable, £1,787. 17s. 3d.; W. T. Henley's Telegraph Works, ditto, £406. 12s. 4d.; Forest City Electric Co., copper bonds, £90; British Westinghouse Co., moulded insulated materials, £98. 3s.; Crystalate Mfg. Co., ditto, £84; British Isola & Micanite Co., ditto, £123. 6s.; Maritime & General Improvements Co., finishing insulating material, £112. 10s.; E. Showell & Sons, car parts, £96. 17s. 3d.; Player & Mitchell, ditto, £86. 17s.; Anti-Attrition Metal Co., bronze bearings, £1,740. 16s. 8d.; Player & Mitchell, machine finished articles (brass, gunmetal, &c.), £227. 17s.; E. Showell & Sons, ditto, £63. 12s.; Anti-Attrition Metal Co., ditto, £154. 6s. 8d.; J. Holroyd & Co., ditto (iron, steel, &c.), £55. 4s.; Bevan Lock Nut Co., ditto, £252. 1s.; Wilkes, Ltd., ditto, £221. 8s.; Horton & Son, ditto, £67. 0s. 6d.; Smethwick Stamping Co., iron and steel stampings, £92. 12s.; J. B. Brooks & Co., ditto, £89. 15s.; Vaughan Bros., ditto, £190. 4s. 2d.; Charles Bunn, ditto, £80. 10s. 4d.; Central Marine Engine Works, ditto, £59. 13s.; Woodall & Co., iron and steel forgings, £92. 2s.; Bayliss, Jones & Bayliss, ditto, £238. 9s.; J. Holroyd & Co., machine iron castings, £50. 10s.; H. Newton, Knights & Co., ditto, £153; J. Crowley & Co., ditto, £67. 3s.; Carron Co., ditto, £255; Rodney Foundry Co., ditto, £108. 6s. 8d.; Wilson, Pease & Co., special iron castings, £241. 10s.; E. Allen & Co., steel castings, £125. 5s.

Hammersmith (London) Council have received the following tenders for steam raising plant:—

Stirling Boiler Co., £5,602, £5,007 and £6,979; Jas. Howden & Co., £5,790, £6,510 and £5,110; Clarke, Chapman & Co., £6,279, £6,686, £6,999 and £8,000; Babcock & Wilcox, £6,713 and £7,613; Fraser & Chalmers, £9,510; British Niclausse Co., (boiler only) £3,490; Hawksley, Wild & Co., £9,602.

The Electricity Committee reported that the most favourable schemes were those submitted by the Stirling Boiler Co. (£5,602) and Fraser & Chalmers (£9,510). In regard to the offer of the latter firm the electrical engineer (Mr. G. Gilbert Bell) pointed out that that furnace was constructed to burn coal dust and the coal was pulverised as required. The labour item was reduced to a minimum. The plant gave a larger output than any other offered. The smoke stack was, however, too short, and an economiser was an essential part of the boiler, the output being reduced about 25 per cent. if dispensed with. After carefully considering the details of this tender Mr. Bell came to the conclusion that the extra price asked outweighed the advantages. The lowest tender, in comparison with the size of the boiler, was that of the Stirling Co., which with hot-air forced draught and all necessary auxiliaries, was £5,602. He recommended that a larger air heater be supplied, and so obtain a greater efficiency. The committee agreed with Mr. Bell's recommendation, and report that it is desirable to obtain the 2½ per cent. higher efficiency guaranteed upon the extra outlay of £229 on large heaters, and that the tender of the Stirling Co. (at £5,602) be accepted, subject to any modifications considered desirable.

Digitized by Google

The following tenders have also been accepted by Hammersmith (London) Council :—

British Electric Transformer Co., two 100 kw. transformers, £179; two 200 kw. transformers, £298; Spagnoletti (Ltd.), 24 panels of substation switchgear, £269; Universal Electric Mfg. Co., supply of fittings for conversion of arc lamps into metallic filament lamps, £25. 185 sets tinned copper joint box connections, £18. 15s., 17 c.i. feeder pillars with switches and fuses, £86. 15s.

Wimbledon Council has accepted the following tenders for annual supplies :—

Western Electric Co., cables and pilot wires; Albion Clay Co., Sykes conduits; Doulton & Co., Doulton conduits; Dussek Bitumen Co., compound; British Insulated & Helsby Cables, tapes, sealing ends and rubber mats; W. Lucy & Co., house service boxes, main and link joint boxes and lead sleeves; Sykes & Sugden, house fuse-boxes; Callender's Co., copper bars and frames and covers; Foster Eng. Co., transformers; General Electric Co., and Ferranti Limited, meters; Siemens Bros. & Co., v.i.r. cables; General Electric Co., accessories; J. & H. Grevener, flame arc lamp carbons.

Watford Council have accepted the tender of W. T. Henley's Telegraph Works Co. for one year's supply of h.t. and l.t. paper insulated cables. Tenders were also submitted by Siemens Bros. & Co., Union Cable Co., British Insulated & Helsby Cables, General Electric Co., Callender's Cable & Construction Co., W. T. Glover & Co., and Johnson & Phillips.

Birchip (Victoria) Electric Supply Co. have accepted the tenders of Pfaff, Pinshoff & Co. (agents for the Ganz Co.) for three panel main switchboard and 500 metallic filament lamps; the Welsbach Light Co. of Australia, for E.C.C. dynamo, booster and rheostat; R. Hornsby & Sons, for 50 H.P. suction gas engine and producer; and Warburton, Franki & Co., for accumulators.

York Council have accepted the tender of the British Thomson-Houston Co. for supply of a 1,000 kw. turbo-alternator, converters and switchgear at £7,451, and the tender of Babcock & Wilcox for the supply of a watur tube boiler, automatic stoker and pipework for £2,080.

The British Westinghouse Electric & Mfg. Co. have been favoured with an order from R. Jeffry (for Pedro Perfetti, Valparaiso, for Tres Marias oficina) for two 75 kw. 230-volt d.c. generators and control gear, one 80 H.P., four 13 H.P., two 31 H.P. 220-volt d.c. motors and control gear.

The Metropolitan Asylums Board has placed an order with W. J. Fryer & Co. for wiring the new operating room in the Park Hospital at £27. 18s., and an agreement has been entered into with Pritchetts & Gold for the renewal of their maintenance of the storage battery at the Grove Hospital for five years at £75 per annum.

Belfast, Barrow and West Hartlepool Corporations have accepted tenders of Venner & Co. for Hookham meters for the ensuing 12 months. Belfast Corporation have also accepted the firm's tender for Venner time switches.

Yarmouth Council have accepted the tender of the British Griffin Chilled Iron and Steel Co. for 60 steel tyres at 34s. each, and that of the British Westinghouse Electric & Mfg. Co. at 52s. 6d. each for 36 gear wheels.

Tonbridge Council have placed orders with the Electrical Apparatus Co. for meters above 5 amperes and with the Bastian Meter Co. for meters up to 5 amperes. The contract for cables has been let to the Western Electric Co.

Marylebone (London) Council has accepted the following tenders :

Babcock & Wilcox, two superheaters, £250 each; Tudor Accumulator Co., additional cells (78) at Manchester-square and Rathbone-place substations, batteries, £2,541.

London County Council have accepted the tender of G. Weston & Sons for electric light fitting at Belvedere-place School, at £275.

London County Council have also accepted the tender of the Frodingham Iron & Steel Co. for 520 tons of rolled steel ties for magnetic brake shoes, at £6. 19s. 6d. a ton and £6. 17s. a ton, according to place of delivery.

Bray (Ireland) Council have accepted the tender of the General Electric Co., Crompton & Co., Cryselco (Ltd.), and Wakefield & Co. for supply of electrical stores. There were 34 tenders.

Gisborne (N.Z.) Council have placed an order with the General Electric Co. for generating plant comprising two Diesel oil engines and two Witton generators.

Yarmouth Education Committee have accepted the estimate of the borough electrical engineer (Mr. G. Bryant) for installing auto-transformers and metal filament lamps at Horthgate schools, at £29. 11s.

Crewkerne Engineering & Foundry have obtained the contract for the electric lighting plant of the Crewkerne Grammar School.

Torquay Council has accepted the tender of the Rees Roturbo Mfg. Co. at £352 for a motor-driven pumping plant.

Penistone Council have accepted the tender of Chapman & Sons for electrically-driven pumping plant at £369

Gloucester Council have placed an order with J. Brown & Co. for tramcar wheel tyres and with the Tyne Metal Co. for brake blocks.

Stockport Council have accepted the tender of Geo. Robson & Co. for a tram rail grinder and driller.

BUSINESS NOTICES.

The Bombay Electric Co. ask us to announce that Mr. Donald Macleod is no longer connected with the company.

Messrs. Wright & Wood, Halifax, have appointed Messrs. Berry, Skinner & Co., 78, Upper Thames-street, E.C., and Mr. Bertram T. Dale, 18, Bigg-market, Newcastle-on-Tyne, as their sole agents for London and district and the North-East Coast respectively for their motors and dynamos, motor-generators, converters and other specialities.

The offices of the Dowsing Radiant Heat Co. have been removed to 105, Gt. Portland-street, London, W.

Messrs. Tetley & Co. have appointed Mr. H. B. Done as their representative for Birmingham and Midlands, with offices at 137A, Suffolk-street, Birmingham.

The Bell Rock Belting Co., Salford, have appointed Mr. James Woolcott as their representative.

John Bullivant and Jas. Lindsay (trading as Lindsay & Co.), electrical engineers, Crown Works, 78, Lees-road, Oldham, have dissolved partnership.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by auction at the Royal Arsenal, Woolwich, at 11 a.m. on Tuesday, April 25, unserviceable and obsolete stores, including iron and steel scrap, brass, gunmetal, lead and antimony, manganese bronze, zinc, &c., electric cable, lathes and tools, pumps, engines, electrical instruments, lamps, &c. May be viewed at the Royal Arsenal, Woolwich, on Friday and Monday, prior to and on morning of sale. Catalogues at the War Office, Whitehall, the Ordnance Office, Tower, and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Patent Development.—The proprietors of patents Nos. 9,413, 9,418, 9,423 and 9,424, of 1906, for "Improvements in pneumatic tube systems" and "Improvements in governing mechanism for pneumatic tube systems," desire to make arrangements, by way of licence and otherwise, for exploiting and developing same in this country. Applications to Messrs. Haseltine, Lake & Co., patent agents and consulting engineers, 7 and 8, Southampton-buildings, London, W.C.

"The Marconigraph."—This is the title of a new monthly publication issued by the Marconi Wireless Telegraph Co. to keep the staff of the company, spread all over the world, in touch with the parent company and officials in London. No. 1 of the new publication (price 2d.) is before us, and the frontispiece is an excellent likeness of Mr. Marconi, who, despite the strenuous character of his labours and the enthusiasm with which he engages upon new problems, and such incidentals as heavy legal cases, does not seem to age. Those of us who remember him in the old St. Margaret's-Wimereux days are almost as surprised at his continued youthfulness as we are at the strides his system has made and the great accomplishments achieved. There is an interesting biographical sketch of Mr. Marconi in the new publication and an interesting budget of news. The illustrations are interesting, and we have no doubt "The Marconigraph" has come to stay.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during March, 1911, and (*b*) during the current year from Jan. 1 to March 31, with the increases or decreases compared with the corresponding periods of 1910 :—

Electrical machinery (*a*) £114,250 (increase £59,975), (*b*) £267,684 (increase £130,265); telegraph and telephone cables (*a*) £33,828 (increase £24,140), (*b*) £91,843 (increase £54,665); telegraph and telephone apparatus (*a*) £13,182 (decrease £3,539), (*b*) £38,944 (decrease £2,957); other electrical wires and cables, rubber insulated (*a*) £10,776 (decrease £1,645), (*b*) £23,739 (decrease £12,501); with other insulations (*a*) £4,699 (increase £1,971), (*b*) £11,552 (increase £5,483); carbons (*a*) £11,115 (decrease £1,227), (*b*) £36,688 (increase £942); glow lamps (*a*) £27,045 (decrease £28,535), (*b*) £85,208 (decrease £54,760); arc lamps and electric searchlights (*a*) £247 (increase £146), (*b*) £429 (decrease £847); parts of arc lamps and searchlights (other than carbons) (*a*) £9,530 (increase £4,535), (*b*) £29,221 (increase £11,847); primary and secondary batteries (*a*) £4,166 (increase £542), (*b*) £13,391 (increase £3,934). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £126,001 (decrease £394), (*b*) £357,550 (increase £9,173).

Digitized by Google

Exports.—The exports of electrical machinery, material, &c. (*a*) during March, 1911, and (*b*) during the current year from Jan. 1 to March 31, and the increases and decreases compared with the corresponding periods of 1910, are as follows:—

Electrical machinery (*a*) £154,891 (increase £36,800). (*b*) £437,710 (increase £119,949); telegraph and telephone cables (*a*) £89,759 (decrease £50,245), (*b*) £195,261 (decrease £547,979); telegraph and telephone apparatus (*a*) £23,291 (increase £11,070), (*b*) £69,605 (increase £34,251); other electrical wires and cables, rubber insulated (*a*) £32,910 (increase £9,122), (*b*) £102,747 (increase £4,550); with other insulations (*a*) £40,464 (increase £19,813), (*b*) £108,140 (increase £61,452); carbons (*a*) £1,535 (increase £820), (*b*) £5,576 (increase £998); glow lamps (*a*) £12,270 (increase £1,541), (*b*) £42,055 (increase £10,225); arc lamps and searchlights (*a*) £1,047 (decrease £482), (*b*) £4,531 (decrease £437); parts of arc lamps and searchlights (other than carbons) (*a*) £1,339 (increase £432), (*b*) £3,461 (decrease £57); primary and secondary batteries (*a*) £17,976 (increase £11,465), (*b*) £31,732 (increase £5,363). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £268,598 (decrease £489,562), (*b*) £697,322 (decrease £1,574).

BANKRUPTCIES, LIQUIDATIONS, &c.

Last week the public examination took place of Charles J. Marrian and Harry E. Wells, lately trading as Marrian, Wells & Co.

Debtors failed in February with joint liabilities £2,758 and no assets, the partners return separate debts of £2,983 and £3,193 respectively. Mr. Marrian stated that the business came to an end in August, 1908, when they offered their creditors, in satisfaction of their claims, shares in the British Photo Lexigraph Co. (Ltd.). They promoted that company in January, 1908, with a nominal captial of £12,500, to acquire and develop an electrical apparatus for advertising purposes. It had been very successful on the Continent, but it was vetoed in London by the London County Council.

A first and final dividend of 5s. 6d. will be payable on April 25 at 152, York-road, Westminster Bridge-road, London, S.E., to the estate of Arthur Driffel Poulter, electrical engineer, &c., late of Alton Lodge, Ewell-road, Surbiton.

A second and final return (2s. 1½d. is payable at 8, Frederick's-place, Old Jewry, London, E.C., to contributories of the Phosphor Bronze Co. (Ltd.), 87, Sumner-street, Southwark, London, S.E.

A meeting will be held at 3, London Wall Buildings, London, E.C., to receive an account of the winding-up of the Allan Electrical Synd. Ltd.

COMPANIES' MEETINGS AND REPORTS.

ALDERLEY EDGE & WILMSLOW ELECTRIC SUPPLY (LTD.)—The profit for 1910 was £2,201, against £1,856 in 1909. The equivalent of 3,283 c.p. lamps was connected during the year, and there are now 434 consumers.

BRISBANE ELECTRIC TRAMWAYS & INVESTMENT CO. (LTD.)—Subject to audit, the revenue account for 1910 (including £1,951. 13s. 6d. brought forward) shows an available balance of £98,014. 18s. 5d., which the directors have dealt with as follows: Payment of debenture interest (£60. 15s.), preference dividend (£17,656. 5s.), an interim dividend of 4s. per share on the ordinary shares (£15,000). Out of the balance (£80. 18s. 5d.) £27,783. 15s. 3d. added to reserve, and a balance dividend of 4s. per share (tax free) is paid on the ordinary shares (making for the year 8 per cent.). £3,506. 3s. 2d. is carried forward.

CALCUTTA TRAMWAYS CO. (LTD.)—The report for 1910 states that the receipts were £186,506, and the working expenses, £106,355, leaving profit, which, with £435 from 1909, makes £80,586. Interest on debenture stock, &c., dividend on preference and ordinary shares paid in advance, share issue account written off absorb £46,842, leaving £33,743. The directors propose to pay a final dividend of 3s. 6d. per share, making 6 per cent. for the year, adding £8,000 to depreciation fund and carrying forward £1,661. The directors report a steady expansion of business, the past year's receipt being a record, but in spite of the larger business, the outgoings show a decrease.

CORK ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—The receipts for 1910 amounted to £55,199. 10s. 7d. and the expenses to £25,670. 17s. 4d., with £514. 9s. 8d. brought forward, and after deducting debenture interest (£4,600) the balance is £18,854. 2s. 11d. The half-year's preference dividends absorbed £6,163. 10s., £5,000 was added to renewal reserve and £1,771. 12s. 4d. written off. The directors recommend 4 per cent. dividend on the ordinary shares (£4,600), leaving £319. 7s. 7d. to be carried forward. The lighting and power business continues to show satisfactory progress. There has been a substantial increase in the number of consumers, agreements for 168 additional connections being concluded during the year for an equivalent of 11,786 c.p. lamps, compared with 9,430 8 c.p. lamps for 1909. There is also increased demand for power. The additional lighting and power connections represent a total gain of 300 kw., against 204 kw. in 1909. The extension to Blackrock and Douglas districts has been completed, and the Co. are satisfactory that the District Council have increased the number of public lamps originally contemplated. The total lighting and power receipts are £1,300 in excess of 1909, and the traffic receipts show an increase of £2,054. The gross profits show an increase of £2,761. To meet increased demands it has been recently necessary to instal an additional 1,000 H.P. boiler and this has been put into satisfactory operation. The capital expenditure during the year has been mainly expended on the Blackrock and Douglas district lighting, additional plant in power station, house services and cables.

DUDLEY, STOURBIDGE & DISTRICT ELECTRIC TRACTION CO. (LTD.)—At the meeting on Monday the chairman (Mr. S. R. Blundstone) said that the result of the working for 1910 showed disappointing results, there being no profit available out of which to pay a dividend on the ordinary shares. The falling off in profits was due to the adverse conditions that prevailed, partly due to the unpopularity of the new system of fares. The system had now been modified to suit local conditions and was working satisfactorily. Further shrinkage in profits had arisen from the fact of the purchase of the Kinver light railway and to the payment to the Birmingham & Midland Tramways (Ltd.) of £59,000.

FOLKESTONE ELECTRICITY SUPPLY CO. (LTD.)—At the meeting last week Ald. Spurgen said there was an increase in the gross receipts of £2,211. That was a larger increase than they had had in previous years since 1903 and 1904. The increase was mainly due to the large hotels adopting their system. The amount available for dividend was £8,949, an increase of £1,358 over last year. They proposed to carry £5,000 to depreciation, because they felt it incumbent upon them to have a substantial sum in the depreciation fund. They had carried £600 to reserve, and proposed to pay 8 per cent. (making 6 per cent. for the year) compared with 5½ per cent. in 1909.

GUILDFORD ELECTRICITY SUPPLY CO. (LTD.)—At the recent meeting Mr. H. P. Smallpiece said the gross receipts had been £7,885, compared with £7,490 for 1909. Expenditure showed an increase of £243, and the gross profit had increased £152. Supply had been extended to Shalford, and the directors felt sanguine that sufficient income would be derived from customers in that parish to well repay the expense incurred. A new battery had been installed of double the capacity of the previous ones, and the directors had decided that the figure at which the old battery stood in the books (£1,432) should be written off this year out of reserve.

INDO-EUROPEAN TELEGRAPH CO. (LTD.)—The directors' report for the year ended Dec. 31 states that the company's traffics continue to show a gratifying increase, and have been carried with the accuracy and speed rendered possible only by the use of direct Wheastone working over the whole system, particularly between London and Karachi. An additional allocation towards the cost of increasing the carrying capacity of the system is proposed. The question of additional cross-channel cable communications is still occupying the attention of the directors. The revenue from message account and other sources amounts to £155,549. 3s. 8d., compared with £145,603. 17s. 5d. for 1909, an increase of £9,945. 6s. 3d. The expenses on commercial and general account are £53,848. 9s. 8d., and on maintenance account, £27,020. 17s., a total of £80,869. 6s. 8d., against £78,296. 3s. 4d. for 1909, an increase of £2,573. 3s. 4d. This, however, includes a special bonus of £3,406 voted by the directors to the commercial and maintenance staffs. The balance is £74,679. 17s., but after deduction of income-tax paid this is reduced to £70,477. 1s. 9d. Adding balance brought forward of £7,978. 1s. 11d., the total is £78,455. 3s. 8d. The sum of £4,627. 13s. 8d. has been provided to meet depreciation of securities. Deducting this sum and the interim dividend of £10,625 already paid, the balance available for distribution is £63,202. 10s. The directors now propose to declare a dividend for the six months ended Dec. 31, 1910, of 17s. 6d. per share (making with the interim dividend already paid 6 per cent. for the year) and a bonus of 20s. per share, both tax free, and to make a special distribution to the shareholders of £12,750, equivalent to 15s. per share, out of interest upon certain investments and advance accounts. This distribution, also, will be tax free. They also propose to set aside the further sum of £20,000 towards cost of increasing the carrying capacity of the system, carrying forward £11,327. 10s.

METROPOLITAN ELECTRIC TRAMWAYS (LTD.)—The Chairman (Mr. E. Garcke) stated at the meeting on Friday that the past year had been one of continued progress, both in regard to the conveyance of passengers and to the business of electricity supply. Four miles of additional line had been opened up, and their system had been brought into contact with the metropolis at a further point. Since the closing of the accounts they had opened up a further line at Ponder's End, joining Enfield with the main line on the Great North-road. They had had running 262 cars, compared with 237 in 1909, and they had found that even that number had been inadequate to cope with the traffic, and had had to hire cars. They had carried 76,000,000 passengers, compared with 62,000,000 in 1909, and the traffic receipts were £393,000, compared with £326,000. The average profit had been larger in the past year than in 1909, £2,417 against £2,342. With regard to electricity supply, carried on by a separate company (of which they held practically all the ordinary shares, £365,000), they had received a dividend of 6 per cent., besides the bonus (£26,000), or rather more than the sum required to pay the dividend on the whole of the company's ordinary shares for the year. The power company supplied 21,000,000 units of electricity during the year, an increase of 30 per cent. Southgate and Kingsbury had been added to the area of supply. They were supplying electricity in bulk to the subsidiary company which had provisional orders in Enfield, Barnet, Hertford and St. Albans, and the business of that company was developing satisfactorily. It paid 4 per cent. for the past year on the shares which the power company held, the first dividend they had received from that company since its property was acquired. The amount spent in repairs and maintenance was £44,500, and they had provided for future renewals to the extent of £21,900. The profit and loss account also included

Digitized by Google

£76,700 paid to the local authorities; and they had reduced the preliminary expenses by £3,000, they had paid debenture and other interest amounting to £35,900, and they had a surplus of £53,767. The board suggested that £8,000 be added to reserve, and after paying the preference dividend (£25,000), a dividend on the ordinary shares of 5½ per cent. (or ½ per cent. more than in 1909) was recommended, carrying forward £2,800. The directors had decided to pay an interim dividend on the ordinary shares. They had practically completed the tramway system as originally designed, only a few small junctions remaining to be completed. With regard to extensions in sparsely-populated districts, they had made experiments and had carefully considered the rail-less traction system, and had come to the conclusion that the system offered a fair substitute for electrical tramways.

SLOUGH & DATCHET ELECTRIC SUPPLY CO. (LTD.)—At the recent meeting the directors reported that 332,295 units of electric current were sold in 1910, against 335,983 in 1909, the equivalent of 17,976 8 c.p. lamps was connected, against 16,380 8 c.p. The total net profit available for distribution was £4,087, out of which £750 was set aside for depreciation. A dividend of 4 per cent. with a bonus of 1 per cent. was recommended. The report was adopted on the motion of the chairman (Mr. H. L. Prior), who gave an analysis of the accounts.

SOUTH STAFFORDSHIRE TRAMWAYS LESSEE CO. (LTD.)—At the meeting on Monday the chairman (Mr. W. S. Schuster) said the profit for 1910 was £253, against a loss of £1,493 in 1909. The introduction of the "fair fare" system had met with considerable opposition, but modifications had been made and the system was now working satisfactorily. The increase in receipts was probably due to the introduction of that system, as the number of passengers carried was nearly 500,000 less. It appeared as if the company had at last turned the corner.

TYNEMOUTH & DISTRICT ELECTRIC TRACTION CO. (LTD.)—The total revenue for the year to Dec. 31 was £13,723. After deducting expenses and debenture interest, and placing £600 to renewals, the surplus was £4,919. The directors recommend that £500 be placed to reserve and £1,000 to sinking fund for debenture redemption, payment of preference dividend, and a ordinary dividend of 4 per cent.

At the meeting Mr. H. S. Day said the trade during the year on Tyneside was unsettled, but a better condition of affairs now prevailed, and he thought they would see an expansion. 2,056,390 passengers has been carried in the company's cars during the past year, compared with 2,044,034 during 1909. The average traffic receipts per passenger had increased 0·07d., chiefly due to the introduction of the "fair fare" system, while the average expenditure per passenger remained the same. The proportion of expenses to receipts had dropped from 60 to 58 per cent.

WILLANS & ROBINSON (LTD.)—At the meeting on Tuesday Mr. James C. Peache, M.Inst.C.E., presided. The Chairman expressed the directors' regret that the accounts again showed an adverse balance due to the deplorable condition of the electrical trade during the last two years or more. Compared with the prices obtainable for turbine plant three years ago the price to-day showed a drop of about 30 per cent., while there had been a considerable rise in the rates of wages during that period. The misfortunes which had befallen the company in the past had left no resources for meeting the present time of adversity. Their shops were fairly well supplied with orders, and although these orders had to be taken on a low scale of prices, yet the returns to be made on this work, if not yielding an actual profit, will be sufficient to provide for the carrying on of the business. Notwithstanding this absence of profit, the directors had considered it right to adhere to the very liberal provision for depreciation which had been traditional in the history of the company. The option for the purchase of Queen's Ferry Works, which ran to November last year, was not taken up, but negotiations were still in progress and there was a fair prospect of their being completed in the near future. The possibility of amalgamation with another concern had been spoken of at previous meetings, and serious negotiations were now in progress. These negotiations might mature into a definite proposition, and if so the scheme would be submitted for their ratification. The proposed changes in the management of the company were set out in the report. They had been very carefully considered, and were commended to the shareholders as effecting a material reduction in their outgoings without impairing efficiency. The report and accounts, as set out in the last issue of THE ELECTRICIAN, were then unanimously adopted.

WINDSOR ELECTRICAL INSTALLATION CO.—The director's report states that the capital expenditure during the year was £4,202, making total £89,313. Profit for the year (£421. 5s. 11d. brought forward) was £5,930. 17s. 7d., and after providing for debenture interest, preference dividend on shares, depreciation, &c. (£1,500), there was a balance of £2,239. 18s. 11d. A dividend of 4 per cent. (less tax) on the ordinary shares allowed £356. 10s. to be carried forward. During the year 1,769 (equivalent) 8 c.p. lamps were connected, the total at Dec. 31 being 47,641 8 c.p. At the meeting last week Sir W. Shipley said the net profit showed an increase of about £500, notwithstanding that the receipts from sale of current were nearly £600 less owing to the introduction of metal filament lamps and other causes. A Diesel oil engine of 100 kw. had been installed.

WOLVERHAMPTON DISTRICT ELECTRIC TRAMWAYS (LTD.)—At the meeting on Monday the chairman (Mr. S. R. Blundstone) said that a severe trade depression had prevailed in the district during a large part of the past year, and the traffic receipts were adversely affected, although they were £500 better off than in 1909.

NEW COMPANIES, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

COUNTY LIGHT (LTD.) (115,067.)—Reg. April 4, capital £7,000 in 6,703 preference shares of £1 each and 5,940 ordinary shares of 1s. each, to carry on the business of contractors for the supply of power, light and heat, &c. Private company. First directors, B. E. Mayhew, C. F. P. Blatchley (chairman), E. Scott Snell, H. E. Cohen and J. R. Horton. Reg. office, Alderman's House, Bishopsgate, London, E.C.

WELLMAN, HEAD, STOTHERT & PITT (LTD.) (115,083.)—Reg. April 3, capital £100 in £1 shares, to carry on the business of ironfounders, mechanical, hydraulic, electrical, telegraph and general engineers, manufacturers of and dealers in steam engines, boilers, &c., and to adopt an agreement with Stothert & Pitt and Wellman, Seaver & Head. Private company. First directors, W. Pitt, P. K. Stothert, B. W. Head and F. I. Sanderson.

MORTGAGES AND CHARGES.

CARMARTHEN ELECTRIC SUPPLY CO. (LTD.)—Issue, on March 25, of £50 debentures, part of a series of which particulars have already been filed.

COWPER COLES ENGINEERING CO. (LTD.)—Issue, on Feb. 27, of £300 debentures part of series of which particulars have already been filed.

LANDAULET CO. (LTD.)—Memorandum of satisfaction in full, on March 30, of debenture dated March 8, 1910, securing £4,000, has been filed. A debenture, dated March 30, 1911, to secure £6,000, charged on company's undertaking and property, present and future, including uncalled capital, has been registered. Holder: F. W. Stanley.

RECEIVERSHIPS.

BAILEY ELECTRIC CARBONISING CO. (LTD.)—Notice of appointment of H. Appleyard, Prudential-buildings, Dewsbury, as receiver, on March 31, 1911, under powers contained in debentures dated Feb. 12, 1909, has been filed.

F. A. GLOVER & CO. (LTD.)—Notice of appointment of A. F. Whinney, 4B, Frederick's-place, Old Jewry, London, E.C., as receiver and manager, by order of court dated March 27, 1911, has been filed.

CITY NOTES.

MEMORANDA (April 12).—**Bank rate 3 per cent. (March 9, 1911) Price of silver, 24⅛d. per oz. Consols 81⅛–81⅜ for money; 79½–79⅞ for account. Consols Pay Day, May 4; Stock and Shares Continuation Days, April 25 and May 10; Ticket Days, April 26 and May 11; Pay Days, April 27 and May 12; Mining Shares Carry Over Day, April 24.**

PRICES OF METALS (London).—*Copper*, cash, 53⅛; three months, 51⅝. *Lead*, English, 13⅛–13⅜; foreign, 12⅝–13 cash, 13⅛–13⅜, three months. *Spelter*, 23½–23¾. *Tin*, English, 190–192; foreign, 192¼ cash, 187½ three months. *Iron*, Cleveland, cash, 47/2, three months, 47/11.

ANGLO AMERICAN TELEGRAPH CO. (LTD.)—The directors have resolved, after placing £5,000 to credit of renewal fund, to declare an interim dividend for the quarter ended March 31 of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock (less tax), payable May 1.

BABCOCK & WILCOX (LTD.)—The directors have declared a further dividend of 8 per cent. (making 18 per cent. for 1910) and also a bonus of 8 per cent. The preceding year's distribution amounted to 24 per cent.

CALCUTTA ELECTRIC SUPPLY CORP. (LTD.)—526,960 units were delivered to consumers during the four weeks ended Feb. 24, compared with 439,285 units in the corresponding four weeks of 1910.

COUNTY OF LONDON ELECTRIC SUPPLY CO. (LTD.)—The transfer books and register of holders of second debenture stock will be closed from the 17th to the 30th inst. inclusive, preparatory to payment of interest due May 1.

DIRECT UNITED STATES CABLE CO. (LTD.)—The board have resolved upon the payment of an interim dividend of 2s. per share (tax free), being at the rate of 4 per cent. per annum for the quarter ended March 31, payable 26th inst.

NORTH OF ENGLAND COAL & IRON INDUSTRIES.—Messrs. Wise, Speke & Co., Newcastle-on-Tyne, have compiled a brochure giving particulars of the financial position of the principal companies and firms engaged in the coal, steel and iron industries. In addition to lists of directors and officials, particulars are given of the share and debenture capital, an analysis of the balance sheets for the past five years, &c.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed April 27 a special settling day in, and granted a quotation to a further issue of $726,200 common stock of the *Canadian General Electric Co. (Ltd.)* The Committee have also ordered 160,000 £1 fully-paid shares of the *Waste Heat and Gas Electrical Generating Stations (Ltd.)* to be quoted.

TELEPHONE CO. OF EGYPT (LTD.)—**The directors recommend a dividend of 6 per cent. (6s. per share), tax free, on the preferred and deferred shares for the past half-year (making 10 per cent. for year), placing £1,000 to reserve for contemplated pension scheme.**

NOTES.

Tramway Accidents.

We are pleased to notice that serious tramway accidents in this country have been much less frequent during the past year than was the case a little time ago. The accident at Highgate on Friday last, however, is a reminder that the problem of controlling a tramcar under all circumstances on steep gradients has apparently not yet been satisfactorily solved. The hill on which the accident in question occurred has previously been the scene of mishaps, and is certainly a dangerous length of track to negotiate, a steep incline terminating in a curve. As the result of a previous accident of a more serious nature, a number of posts have been erected at the foot of the hill to prevent any cars that may leave the rails from dashing into the shops opposite; on the present occasion, however, the derailed car collided with an electric standard, fortunately without such serious results as might have been anticipated, the traffic at the time being comparatively light.

In view of previous accidents at this spot we expect that the braking equipment of the cars has received particular attention, but it would seem that the precautions taken for operating the cars safely on this hill are still insufficient. As the necessity of more powerful control on steep gradients, particularly in view of the heavier cars now employed, is widely felt, it is interesting to note that the slot rails of the conduit have been successfully employed during the past year for braking purposes on a short length of track of the London County Council tramways at Highgate Hill. Cast-iron brake blocks operate against the upper and lower surfaces of the slot rails (these being strengthened for the purpose) and are hand-operated by a cam coupled to hand wheels on the front and rear platforms of the cars. The slot brake gear is raised or lowered in a special hatchway at the foot of the hill, and as the cars are provided with magnetic track and hand wheel brakes in addition, there should be little chance of a car attaining a dangerous speed. With the overhead trolley system this additional means of braking is not available, but we do not doubt that dangerous gradients will be avoided in future, certainly where the danger in the case of a car getting out of control would be increased by a sharp curve at the foot of the gradient.

High Candle-power Metal Lamps.

A NUMBER of the manufacturers of metal lamps are making announcements this week of reductions in the prices of the higher candle-power sizes of lamp. This is a development which is not altogether unexpected, and we feel sure that it will be welcomed by the industry generally. The movement must not be regarded as an attempt to cut prices, because it does not affect what may be described as the domestic pattern of lamp. After all, the electricity consumer is deriving immense benefit from the metal lamp and he can hardly expect to purchase the smaller sizes at prices proportional to the candle-power. The new

Digitized by Google

prices introduced by lowering the initial cost of the high candle-power lamp, will enable tradesmen and central station engineers more effectively to meet the competition of the inverted gas mantle. The standardisation of fittings in which clusters of, say, 100 c.p. metal lamps can be used has encouraged the tradesman to employ this class of illuminating unit for both interior and exterior shop lighting. In this direction the gas interests are especially active, and while we shall not discuss for the moment the methods which they adopt to persuade the tradesman to fit gas lanterns or "gas arcs," we shall be content with saying that with high candle-power metal lamps at the new price the electrical contractor and central station engineer will be able to do infinitely more in this field than previously.

In the province of street lighting this development will be of enormous assistance to electricity supply authorities in the vigorous campaign which they are waging against gas. The price of the high candle-power metal lamp has, after all, an important bearing on the general cost of street lighting by electricity, and the station man who has been hitherto unable to recommend the conversion of gas lanterns or the equipment of new posts with metal lamps mainly on the score of high cost will be in a better position to proceed. We should be glad to hear from station engineers upon this point, and should welcome their opinion on the difference which the new prices will make in the furtherance of any scheme that they may have in hand. The coming winter will see the competition between gas and electricity at its keenest, and we are anxious to publish facts which will assist the station engineer and the electrical contractor in the conduct of this important campaign.

A Street Lighting Compromise.

Our readers will learn with interest that the lion and the lamb are lying down together in amity even before the advent of the millenium; in other words, without specifying which is the lion and which the lamb, the Metropolitan Electric Supply Co. and the Gas Light & Coke Co. have joined hands in tendering for the lighting of the Holborn district instead of continuing a cut-throat competition. Although some electrical engineers might prefer open antagonism to the gas industry, the compromise reached by the two competing companies in this case will doubtless be generally welcomed; the more so, since it may act as a salutary lesson to those Councils which have a weakness for playing off competing interests against one another. It must surely have come as a bombshell to the Holborn Borough Council at their meeting last week to find a joint communication and tender from the two Companies concerned, submitting a scheme for lighting the borough partly by gas and partly by electricity. Moreover, the Companies have actually dared to dictate to the Council as to certain onerous clauses of the specification. Under such circumstances it is rather surprising to find that the joint scheme is to cost the Council less than the amount of the original tender recommended by the Works Committee for acceptance; but the explanation is perhaps to be found in the fact that the Companies refuse to adopt improved burners, lamps or appliances unless the Council agree to pay the extra cost entailed by such improvements, and that the penalties mentioned in the specification will not be enforced. In the event of the Council determining to adhere to these penalties the contract price is to be increased by 10 per cent. The tender has been referred to the Works Committee for report, the Council to consider such report in committee, so that the public and the press will doubtless be deprived of much entertaining recrimination.

Reliability of Overhead Lines.

At a time when much attention is being paid to the development of transmission lines in this country it is interesting to read in a recent issue of the "Electrical World" some editorial remarks on the experience of a correspondent as set forth in an article in our American contemporary. The supply company with which the writer in question was connected purchased energy in bulk, the energy having to be transmitted over a considerable distance. Their experience seems to have been particularly unfortunate, for in one year no less than 120 interruptions of supply were recorded, totalling over 90 hours. The energy was generated by hydro-electric plant but this was not at fault, the troubles arising in practically all cases in connection with the transmission of the energy more especially as regards the failure of subsidiary apparatus and on the branch lines. A duplicate transmission line moreover, did not provide the security against failures that was anticipated, the writer describing it as a "snare and a delusion." Surges on the lines and sudden fluctuations of voltage frequently resulted in the synchronous machinery falling out of step, in addition to failures caused by storms, broken insulators and discharges over lightning arresters. The company finally found it desirable to instal a steam plant and to use the transmitted energy as a stand-by.

Our contemporary remarks that "if the solemn truth were told the records of interruptions on many transmission lines would not make pleasant reading," although "some companies by the exercise of eternal vigilance, succeed in getting through the year with remarkably clean records. Allowing for the fact that transmission distances are greater and pressures higher in the States than in this country, such a state of affairs would not be tolerated over here, particularly in view of the keen competition of other forms of power. Reliability of supply is invariably considered as of first importance by engineers in this country, and that overhead transmission lines can be made reliable is proved by the satisfactory experience of the Newcastle-on-Tyne and Yorkshire Power Companies.

Wireless Station at Wick.—It is officially announced that the wireless station at Wick is now almost completed. During the progress of the work rigid secrecy has been maintained regarding the design, machinery and equipment of the station, but it is understood that the installation is made in connection with the systematic control of the fleets operating in northern waters, and especially from the naval bases at Scapa Flow, Orkney, and the Cromarty Firth.

Old "Ferrantians" Dinner.—This will be held on Saturday, [illegible] 29th, at the Trocadero Restaurant, London. Mr. C. P. [illegible] will be in the chair.

Railway Electrification.—A meeting of the Joint Committee of the East London Railway Co. will be held on Wednesday next, to consider the question of electrification. Reports of engineers as to cost and methods of electrification are to be discussed.

The Telephone as an Aid to Business.—According to the "Telephone Engineer" a large wholesale lumber dealer [illegible] states that during the past year he has sold about [illegible] feet of lumber, fully 1,500 of which were sold by means of long-distance telephone calls, the sales aggregating more than [illegible].

German Arc Lamp Patents.—We are informed that in the [illegible] between the Deutsche Beck-Bogenlampen-Gesellschaft of Frankfort and the Regina Elektrizitäts Gesellschaft of [illegible] it was decided, on March 27th, that the claim of the [illegible] to have patent No. 156,363 (issued to the Beck Co.) set [illegible] was disallowed. We understand that the ground of the [illegible] was on account of prior publication of the patent in [illegible].

30-ton Electric Locomotive.—"Engineering News" [illegible] 30-ton electric locomotive for heavy goods service. It [illegible] 100 H.P. 700 volt direct-current interpole motors, [illegible] fitted with forced ventilation. The equipment will [illegible] double-end multiple-unit control and combined straight [illegible] automatic air brakes. The engine is designed to handle [illegible] load of 400 tons (behind the engine) at 17½ miles per [illegible] an average gradient of 0·7 of 1 per cent.

Best Thickness for Laminations.—In a communication to "Elektrotechnische Zeitschift," Mr. E. Jasse deduces the [illegible] suitable relation between the thickness of the steel [illegible] in laminated cores and the thickness of the [illegible] separating them. The Steinmetz equation for the [illegible] is assumed, and it is found that this will be a minimum [illegible] the thickness of the sheet bears to the thickness of the [illegible] in the same ratio as four-fifths of the hysteresis loss [illegible] the eddy-current loss.

The Post Office and Telephones.—The forthcoming transfer [illegible] the telephone service to the Post Office has aroused a [illegible] criticism of that department, as may be gathered from [illegible] of THE ELECTRICIAN for the past few weeks. The [illegible] for the other side has now been put by Mr. John Lee, [illegible] Traffic Manager at the Post Office (who was, however, careful to say that he spoke unofficially), in an address [illegible] before the Liverpool Chamber of Commerce last [illegible]. Mr. Lee defended the Post Office from the charge of [illegible] tardiness, and pointed out that that department provided [illegible] a service unequalled by any other country in the world, [illegible] contributed some £4,000,000 yearly to the revenue of the [illegible]. In dealing with the trunk telephone system the [illegible] pointed out that the number of messages was now five [illegible] that it was in 1897, the year after the Post Office had [illegible] over, while the revenue per mile had increased from [illegible] 26 12s. A brief consideration of the development of [illegible] telephony showed that the Post Office were not [illegible] unenterprising as had been stated. As in the case [illegible] telegraph, the Telephone Department was now engaged [illegible] building up an organism, and every small place would have [illegible] access to the main system of working. The purpose of [illegible] was to divide England into zones, and to give pre[illegible] the same service to each place in the zone, whatever its [illegible] distance. The result would be the creation of a [illegible] whereby the period of waiting for a call was consis[illegible] based upon radial distance. American telephone offi[illegible] studying that system with a view to its adoption. [illegible] American theory was that the public preferred a prompt [illegible] to distant routes at a high charge to a slower service at a [illegible] But he was sure of this—that, wonderful though [illegible] telephone service was in America and splendidly [illegible] it was, if the Post Office attempted to establish such a system in England it would be the signal for protest by the public. The fee for a call from New York to Boston, 200 miles, was 5s., as compared with 2s. from Liverpool to London; the fee from New York to Philadelphia was 3s. for 83 miles; in England the Post Office gave communication over a distance of 100 miles for 1s. The same development was taking place in the short-distance services. Wonderful new apparatus had recently been devised, and changes of immense importance were inevitable. The department were studying the influence of these devices on tariffs, and always protecting the interests of the small consumer. In America telephone interests were seeking a way to merge all the telephone interests into one vast State-controlled organisation. Private and competitive enterprise in telephones there, as here, had reached its limit, and the public were putting forward stronger claims, while inventive genius was making apparatus obsolete at such a rate that expenditure of capital would be entailed on a scale which no private company could possibly undertake.

Train Despatching by Telephone in Canada.—The "Engineer" announces that the Canadian Pacific Railway Co. have decided still further to increase the method of train despatching by telephone over its system, and authority has been given for the equipment this year of 1,528 additional miles. This will make a total of 3,782 miles of telephone train-despatching circuits. In connection with the installation of the system, two new copper wires are erected, each weighing 200 lb. per mile, while in the stations the very best apparatus obtainable is used. On all sections where there are telephone train-despatching circuits every train, whether passenger or freight, is equipped with a telephone set and a jointed pole, by which, in case of necessity, telephonic communication with the train despatcher for the district can be established almost immediately, and, in the event of a train being "stalled" between stations, a great deal of delay in obtaining assistance is avoided. These train telephone sets are also used a great deal by goods trains at sidings where there is no regular train operator, and frequently many hours' delay to a freight train is saved.

Electric Locomotive for the Pennsylvania Railroad.—The "Electric Railway Journal" states that nine more electric locomotives, aggregating in capacity about 40,000 H.P., have been ordered by this Company. They will be of the same type as those which are now being operated in the Manhattan Terminal, New York city, and will supplement the 24 already in use. These locomotives are said to be the most powerful ever built for electric working. They are articulated machines of double cab design. Each half carries its own motor and complete equipment, and the two halves are coupled together at their driving-wheel ends. The frames, driving wheels and trucks of the running gear are similar in general character to those of the "American type" steam locomotive. The coupled ends are fitted with permanent couplings of twin drawbars and friction draught gears, so arranged that the front half serves as a leading truck and the other half as a trailer in whichever direction the locomotive may be moving. Each cab is complete with automatic and air brake equipment, apparatus for train lighting, electric headlights, pneumatically operated whistle and sanders, as well as its motor, unit switches and master controller. The machines are so arranged that if one motor is cut out the entire machine can be operated from either cab with the remaining motor. The halves are interchangeable. The unit switch field control permits two or more locomotives to be coupled together, and all to be operated from either end of any one cab, and affords flexibility of speed regulation. It gives two additional running notches and at the same time economises power consumption during acceleration. The normal full speed with a full train is 60 miles an hour, and a 550-ton train can be started on a 2 per cent. gradient by exerting the maximum contract horse-power of 4,000.

"The Present Position of Electric Traction on Main Lines in Europe."—A Paper with the above title was read by Mr. J. B. Sparks on April 12th, before the Students' Section of the Institution of Electrical Engineers. The author gave the

Digitized by Google

main conclusions of the various Government Commissions appointed to consider the introduction of electric traction on main line railways, and summarised the present position in Europe as detailed briefly in the following abstract. In Germany, the Prussian authorities have adopted the single-phase system at 10,000 volts, 15 cycles, and a large sum of money has been granted for the equipment of some 95 miles of double track between Magdeburg, Leipsic and Halle. A 16-mile section of this line has already been equipped and several different types of locomotives are undergoing trials. Some 180 miles of line in Silesia will also shortly be equipped on the same system. The State Railway authorities of Bavaria and Baden respectively have also adopted the single-phase system at 10,000 volts, 15 cycles; and short main line sections between Salzburg and Freilassing, in Bavaria, and between Basle and Zell, in Baden, are already being equipped. Plans have also been prepared by both States for the conversion of a large number of other lines. The Austrian State Railways will shortly have 29 miles of line near Trieste working on the single-phase system at 10,000 volts, 15 cycles, and plans have been prepared for a large number of main lines south of the Danube. The Austrian South Railway Co. intend to introduce three-phase traction on certain of their lines, and the same system may be employed for some of the State railways. A new main line, to be worked on the single-phase system at 10,000 volts, 15 cycles, is being constructed in the north-east of Austria to provide an additional connection between the railway systems of Bavaria and Austria. The Hungarian State railways will shortly have an important suburban system at Budapest, working electrically at 10,000 volts, 15 cycles, single-phase, and a portion of the main line between Prague and Vienna is also to be equipped shortly. Plans are also ready for a 56-mile section of the important line between Fiume and Budapest. The Swiss Federal Railways have decided to adopt the single-phase system at 15,000 volts, 15 cycles, and the St. Gothard Railway will probably be the first to be equipped. A short section of the Loetschberg Tunnel line, now under construction, is already working electrically on this system. The equipment of the Simplon line, which is worked at 3,000 volts, 16 cycles, three-phase, is to be extended at the Italian end of the line. The conversion of the 12-mile Giovi Tunnel line to 3,000 volts, 16 cycles, is practically completed, as is also the Mont Cenis Tunnel line. A number of other main line sections are shortly to be converted, but not necessarily on the three-phase system. The French State railway authorities are considering the introduction of electric traction on lines near Paris, and will assist in the conversion of the belt line just inside the fortifications. The Chemins de Fer du Midi have adopted single-phase at 12,000 volts, 16 cycles, and are already equipping a 70-mile main line section between Pau and Montrejeau, while it is probable that the whole 250 miles of line between Toulouse and Bayonne will be working electrically in a few years. The P.L.M. Co. are making experiments on an electrically equipped track at Grasse, and have in view the conversion of the main line section between Cannes and Ventimiglia. The Swedish State Railway authorities have also adopted the single-phase system at 15,000 volts, 15 cycles, and an 80-mile line in the North is being equipped. Plans have also been prepared for the conversion of the whole system of lines south of Stockholm, and the necessary water power has been secured. In Norway, a 30-mile line is being converted to single-phase working at 10,000 volts, 16 cycles. The author also referred to the proposed conversion of railways in Denmark, Russia and elsewhere, and concluded with some notes on the possibility of the introduction of electric traction upon the main lines of this country.

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910
Latakia—Palura	May 26, 1910
Tourane - Amoy	Sept 25, 1910
Port de France—Paramaribo	April 10, 1911
Bonny—Duala	April 16, 1911
Zanzibar—Mombasa	April 19, 1911

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. G. F. C. Searle concludes his article entitled "On Resistances with Current and Potential Terminals."

We publish an article summarising the methods of protecting high-tension systems.

The Tramways and Light Railways Association have issued a report on "Speed Indicators for Tramcars." This subject is discussed in our Leading Article.

At a recent meeting of the Royal Photographic Society Messrs. J. S. Dow and V. H. Mackinney read a Paper on "Photography and the Measurement of Brightness."

We give an account of the discussion on Mr. W. B. Woodhouse's Paper on "Public Electric Supply in Country Districts."

The Tramways Committee of Manchester Corporation were able to report a satisfactory increase of income over the amount of the original estimate for 1910. £75,000 is again to be contributed to the rates from this source.

Manchester Electricity Committee have decided to hand over £19,496 (1 per cent. on the capital outlay) in relief of rates.

An interesting contract between Stockton-on-Tees Corporation and Messrs. Head, Wrightson & Co. is reported.

A list is issued of the successful candidates at the recent examination for 1st class certificates of the Association of Mining Electrical Engineers. We have received no official intimation of this examination or its result, and publish the list subject to confirmation.

The extraordinary position taken up by the Aldershot Gas Co. in regard to preferential treatment of non-users of electrical energy is recorded elsewhere.

A good demonstration of the utility of electric driving in emergencies was afforded last week at Messrs. Rennie & Co.'s mills at Stanningley. The works were rendered idle by the failure of a steam engine on Wednesday, and within 24 hours the Yorkshire Electric Power Co.'s supply was connected and the first motor set to work.

Haslingden Council propose, on the expiration of their agreement with Accrington Corporation, to supply current to their tramways from their own distributing station, for which purpose they are seeking powers to borrow £8,750.

At the meeting of Holborn (London) Council last week it was reported that a joint tender for public lighting had been received from the Metropolitan Electric Supply Co. and the Gas Light & Coke Co. After discussion, the matter was referred to the Works Committee for report to the Council in committee.

Beckenham Council have received sanction to a loan of £5,000 for free wiring, &c. An interesting return as to the number of houses wired has been made to the Council.

On the subject of the proposed Telephone Authority, the Postmaster-General (Mr. H. Samuel) made a statement at a dinner at Cardiff on Monday.

Legal.—Mr. Pollock, Official Referee, has given judgment in the action brought by Mr. H. Cruse and others against Messrs. Willans & Robinson for damages for alleged breach of contract in regard to the manufacture of superheaters, and has awarded plaintiffs £3,535 damages, with costs.

Companies' Meetings and Reports.—At the meeting of the Anglo-Argentine Tramways Co. last week the chairman gave an interesting account of the development of the tramway system of the Company and supplied some particulars of the scheme for the construction of subways in Buenos Ayres.

The directors' report of the Deutsch-Atlantische Telegraphen gesellschaft for 1910 is abstracted in another column.

The directors' report of the San Paulo Electric Tramways, Light & Power Co. gives particulars of the electric lighting and tramway undertakings of the Company.

At the recent meeting of Clayton & Shuttleworth, the chairman Col. F. Shuttleworth, said the directors had adopted electric driving throughout the works, and had secured advantageous terms from Lincoln Corporation for the supply of electrical energy.

PERSONAL NOTES.

It is officially announced that Mr. J. W. Meares, electrical adviser to the Government of India, is granted 7½ months combined leave from March 23, or any subsequent date, and Mr. R. J. Browne, electrical inspector to the Government of Bengal and Eastern Bengal an

Digitized by Google

Assam has been appointed to officiate as electrical adviser to the Government of India during Mr. Meares' absence, or until further orders.

New Zealand Government intend to carry out large telephone construction works, and Mr. T. Buckley, chief electrician of the Post and Telegraph Department, will visit England to investigate the latest types of telephone equipment and installations.

APPOINTMENTS VACANT AND FILLED.

An electrician is required to take charge of an electric lighting installation and control of three assistants at a North of England textile factory. See an advertisement.

A young electrical engineer, with thorough college and shop training and some knowledge of the requirements of collieries and iron and steel works, is required for the mining department of a large Continental electricity works. See advertisement.

Two or three draughtsmen are wanted by a large electrical firm. See an advertisement.

The Electrical Power Storage Co., 4, Great Winchester-street, London, E.C., require a qualified sales manager. Applicants must have had experience of storage batteries, and possess a good connection. See an advertisement.

A thoroughly reliable estimator is required in a leading firm of manufacturing electrical engineers in the Midlands.

An assistant master is required to assist in teaching mathematics and science (physics and chemistry) at the South African College School, Cape Town. Salary £250 per annum. Applications to the Secretary by May 3.

A lecturer in applied mathematics is required for the Grey University College, Bloemfontein. Salary £400 per annum. Applications to the High Commissioner for South Africa, 72, Victoria-street, London, S.W., by May 19.

The Wrexham Local Higher Education Committee require a director of the technical schools. Salary £220, rising to £250 per annum. Applications to the Clerk to the Governors by May 16.

Mr. Alfred Bremner, M.I.E.E. (late of Burslem), has been appointed assistant electrical engineer of the Walsall Corporation electricity works. Mr. Bremner will act as borough electrical engineer during the absence of Mr. A. S. Barnard, who has six months' sick leave.

Mr. J. Cotton, B.Sc., has been appointed assistant lecturer in mechanical electrical engineering for the remainder of the present session at the Technical College, Huddersfield.

Mr. J. F. Tivey, of Sydney University, has been appointed assistant lecturer and demonstrator in engineering at Queensland University.

Mr. A. Goodall has been promoted to the position of chief assistant electrical engineer at Devonport electricity works, in succession to Mr. Stamp, who recently left for Canada.

INSTITUTIONS AND SOCIETIES.

Royal Institution.—The arrangements at this institution for the remainder of the session include the following courses: On Thursday, April 27th, Prof. R. W. Wood, of the Johns Hopkins University, will begin a course of three lectures on "The Optical Properties of Metallic Vapours," these being the Tyndall Lectures. The Friday evening course on April 28th will be delivered by Prof. W. M. Flinders Petrie, F.R.S., on "The Revolutions of Civilisation"; on May 5th by Prof. M. O. Forster, F.R.S., on "New Organic Compounds of Nitrogen"; and on May 12th by Prof. William Stirling, on "Physiology and the Cinematograph."

Physical Society.—ERRATUM.—We have been asked to state that the meeting of this Society on March 24th was held at the City and Guilds (Engineering) College. This is not clear from the account in our issue, as reference is only made to the Imperial College of Science.

Faraday Society.—At the meeting of the Faraday Society to be held on Tuesday, May 2nd next, Mr. A. Scott-Hansen, the well-known American engineer, will deliver a lantern lecture on "Hydro-electric Plants in Norway, and their Application to Electrochemical Industries." On the same evening a Paper is down for reading by Mr. Walter Cutts, of Sheffield, entitled, "Electrometallurgy in the Sheffield District." The Society meets at the Institution of Electrical Engineers, Victoria Embankment, W.C., and the secretary, Mr. Alfred Gradidge, 62, Victoria-street, S.W., will be glad to send cards of admission to anyone interested desirous of attending the meeting.

Glasgow Section of the Institution of Electrical Engineers.—At the meeting of the above Section on Tuesday, April 11th, the following council were nominated for the session 1911-12: *Chairman*, Mr. F. A. Newington; *vice-Chairman*, Mr. Jas. Lawson; *hon. sec.*, Mr. Jas. E. Sayers; *Committee*, Messrs. Wm. McWhirter, T. B. Murray, T. C. Parsons, Jas. Ferguson, D. A. Starr, Lee Murray, J. A. Robertson, Prof. Magnus McLean and Dr. Jas. T. Bottomley, F.R.S. The chairman intimated that the Council of the Institution had acquiesced in the Local Section's request that the Section in future be known as the "Scottish Local Section."

EDUCATIONAL NOTICE.

Crystal Palace School of Practical Engineering.—The usual term distribution of certificates to the students of this school took place on Wednesday, April 12th, when the Right Hon. Sir George Reid, High Commissioner for Australia, presided and addressed the students.

The "Wilson" premium for the best Paper read before the Engineering Society (affiliated to the Society of Engineers) during the session has been awarded to J. F. Ormsby, for his Paper on "Liquid Air." Other Papers read during the session were: "Locomotive Superheaters," by F. E. Wright: "Roads," by C. M. H. Sheridan; "Tube Railways," by G. H. Henfrey; and "Sanitation," by A. Zammar.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, April 22nd.

NEWCASTLE BRANCH OF THE ASSOCIATION OF MINING ELECTRICAL ENGINEERS.

2 p.m. Visit to the Electrical Installation at Chopwell Colliery.

MONDAY, April 24th.

ILLUMINATING ENGINEERING SOCIETY.

8 p.m. Meeting at the Royal Society of Arts, John-street, Adelphi. Papers on "The Ratio of Light to Illumination," by Mr. Haydn T. Harrison, and "Some Notes on the Effect of Wall Papers upon the Illumination of Interiors," by Mr. P. J. Waldram.

TUESDAY, April 25th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Meeting at Great George-street, Westminster. Annual General Meeting.

NATIONAL ELECTRICAL MANUFACTURERS' ASSOCIATION.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment, W.C. Paper on "Foreign Compared with Home Industrial Finance," by Mr. L. Joseph.

WEDNESDAY, April 26th.

ELECTRICAL TRADES BENEVOLENT INSTITUTION.

7 p.m. for 7:30 p.m. Festival Dinner at the Hotel Cecil, London.

STUDENTS' SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

7:45 p.m. Meeting at Victoria Embankment. Paper on "Single Phase Commutator Motors, especially the Latour-Winter-Eichberg Motor," by Messrs. H. Page and C. J. Scott.

BIRMINGHAM SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at the University, Edmund-street, Birmingham. Paper on "Battery Economies and Battery Discharge Arrangements," by Mr. A. M. Taylor.

THURSDAY, April 27th.

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Lecture on "Optical Properties of Metallic Vapours," by Prof. R. W. Wood. Tyndall Lecture I.

INSTITUTION OF MECHANICAL ENGINEERS.

7 p.m. for 7:15 p.m. Anniversary Dinner at the Hotel Cecil, London.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at Victoria Embankment. Paper on "Battery Economies and Discharge Arrangements," by Mr. A. M. Taylor.

FRIDAY, April 28th.

PHYSICAL SOCIETY OF LONDON.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "High-Tension Electrostatic Wattmeters," by Prof. E. Wilson; "Previous Magnetic History as Affected by Temperature," by Prof. E. Wilson and Mr. L. C. Budd; "Note on the Behaviour of Incandescent Lime Cathodes," by Dr. R. S. Willows and Mr. T. Picton; "On the Formation of Dust Striations by an Electric Spark," by Dr. S. Marsh and Mr. W. H. Nottage.

STUDENTS' SECTION OF THE INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Meeting at Great George-street, Westminster. Lecture on "The Commercial and Technical Relations of Engineering Design and Work," by Mr. T. Frame Thomson.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "The Revolutions of Civilisation," by Prof. W. M. Flinders Petrie, F.R.S.

Digitized by Google

HIGH-TENSION CABLES.*

BY DR. PAUL HUMANN.

Ten years ago a voltage of 10,000 was considered as the outside limit for which a cable could be constructed for everyday work, and even so at this pressure there had been some unpleasant experiences of a costly nature. Lately, however, cables for a working pressure of 20,000 volts have been put in operation without any very noteworthy difficulties, and enquiries are occasionally made for cables to be used on 40,000 and even 60,000 volts. Very little, comparatively speaking, seems to have been published on the subject of the construction of cables for lighting and power work; and it may therefore be of interest to give some outlines relating to the dimensions of high-tension cables.

The purchase of a high-tension cable is a matter full of uncertainties, and this obviously ought not to be the case. For instance, if enquiries were to be made of a number of manufacturers for cables, suitable for a working pressure of 30,000 volts, the prospective buyer would make the curious discovery that some makers increase the thickness of the insulation with an increase in the diameter of the conductor, while others do the reverse. In 1908 Dr. Apt showed, as a corollary to O'Gorman's theory, that the thickness of the insulation should decrease as the diameter of the conductor increases. Considering the matter theoretically, let us take first the simple case of a cable with a single conductor and with an insulation of a uniform nature, such as is approximately the case with those constructed of impregnated paper. The insulation can then be considered to consist of a series of concentric layers of very small thickness; each layer, therefore, constitutes a condenser, a large number of which are therefore placed in series with one another. The capacity of the layer at a distance x from the centre and of a thickness dx is given by the equation

$$C_x = \frac{c \cdot L \cdot 2 \cdot \pi \cdot x}{4 \cdot \pi \cdot dx} = \frac{c \cdot L \cdot x}{2 \cdot dx},$$

where c is the dielectric constant, and L is the length of the cable. The capacity of the cable between the conductor and lead covering is, therefore,

$$C = \frac{c \cdot L}{2 \log \frac{R}{r}},$$

where R and r are the external and internal radii of the insulation. If we denote the voltage between the conductor and lead covering by E, and remember that the voltage across a layer is inversely proportional to the capacity, we get the following relations, viz.:—

$$\frac{dE}{E} = \frac{\frac{c \cdot L}{2 \log \frac{R}{r}}}{\frac{c \cdot L \cdot x}{2 \cdot dx}} = \frac{dx}{x \log \frac{R}{r}},$$

$$\frac{dE}{dx} = \frac{E}{x \log \frac{R}{r}} = \frac{E}{2{\cdot}3 \cdot x \log_{10} \frac{R}{r}}.$$

The value of $\frac{dE}{dx}$ gives the potential gradient and has a maximum value when $x = r$, and this value may be called e. The fall of voltage on the inner surface of the insulation is a factor of the first importance. If the thickness of the insulation is denoted by δ, then we can deduce from our formula the following equation, viz.:—

$$\log R = \log (r + \delta) = \frac{E}{2{\cdot}3 \cdot r \cdot e} + \log r,$$

and this enables us to determine the relation between the thickness of the insulation and the diameter of the conductor. It must be emphasised that these equations apply only to a homogeneous dielectric, and this is not necessarily the case with a cable the insulation of which has been submitted to a series of impregnations, and cases also arise where designedly a differential treatment has been adopted. Let ϵ denote the ratio between the working voltage E and the specific tension across the innermost layer, or expressing all quantities in millimetres, the ratio of E to e. Then the last equation becomes

$$\log (r + \delta) = \frac{\epsilon}{2{\cdot}3 \cdot r} + \log r,$$

and from this it is easy to calculate the thickness of the insulation δ and the overall diameter of the cable, *i.e.*, the internal diameter of the lead covering. Taking the value of e as 2,000, we can calculate the values of δ for working voltages of 10,000, 20,000 and 40,000 and for different values of the diameter of the conductor. The following table gives the resulting figures:—

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Table I.

r in mm.	Thickness of insulation in mm.			Overall diameter of cable in mm.		
	$\epsilon = 5.$	$\epsilon = 10.$	$\epsilon = 20.$	$\epsilon = 5.$	$\epsilon = 10.$	$\epsilon = 20.$
1	148·0	22,400	$500 \cdot 10^6$	298·0	44,800	$1{,}000 \cdot 10^6$
3	12·9	81·5	2380·0	31·8	169·0	4,766·0
5	8·6	32·1	270·0	27·2	74·2	550 0
7	7·3	22·3	116·0	28·6	58·6	246·0
9	6·7	18·3	74·2	31·4	54·6	166·4
11	6·3	16·3	56·8	34·6	54·6	135·6
13	6·1	15·1	47·6	38·2	55·2	121·2
15	5·9	14·3	42·0	41·9	58·6	114·0
20	5·7	13·0	34·5	56·4	66·0	109·0
25	5·6	12·3	30·7	61·2	74·6	111·4
30	5·5	11·8	28·5	71 0	83·6	117 0
40	5·4	11·4	26·0	90·8	102·8	133·0

From this we see that under all circumstances, the radial thickness of the insulation decreases as the diameter of the conductor increases, the value of δ tending to approach the value of ϵ. Very small diameters of conductor are impossible with very high tensions. With low-voltage cables there is something to be said on mechanical grounds for increasing the thickness of the insulation on the bigger cables; but if several millimetres are necessary in any case on electrical grounds, mechanical considerations are of no importance. For each value of ϵ there corresponds a radius, r, which gives a minimum overall diameter to the cable, and if the values are plotted out on curves it will be found that when r is equal to ϵ the cable will have a minimum size. The same result is, of course, obtained by differentiating the last equation given above, and equating the differential quotient to zero. This does not necessarily mean that the said cable can be made for the lowest price, and probably one with a

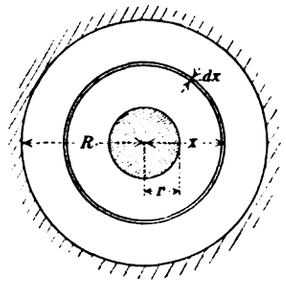

FIG. 1.

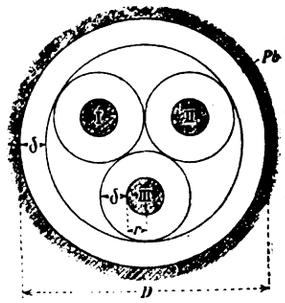

FIG. 2.

slightly smaller diameter would be better in this respect. For very high voltages the smallest overall diameter may correspond to a conductor much bigger than is actually required. In such cases the conductor can be made hollow by winding the strands of copper round a core of hemp, or aluminium may be employed, which has 1·7 times the specific resistance of copper.

The foregoing argument applies only to single cables, and for three-core cables, used with polyphase current, things are undoubtedly more complicated. In order to determine the equipotential surface in the dielectric, an elaborate theoretical investigation is necessary. Let us suppose that, as in Fig. 2, there is an equal thickness of insulation between the conductors themselves and between the conductors and the lead sheath. In this case the overall diameter under the lead is given by the equation

$$D = 4{\cdot}31 \cdot r + 6{\cdot}31 \cdot \delta.$$

The thickness δ of the insulation is given by the equation

$$\log (r + \delta) = \frac{\frac{E}{\sqrt{3}}}{2{\cdot}3 \cdot e \cdot r} + \log r,$$

where E is the line voltage and the conductors are supposed to be joined up on the star system. From the values in Table I. it is possible to draw up figures for the case of the three-core cable. The results are shown in Table II. It must be noted that here ϵ is the ratio of the voltage across the star-connected conductors to the voltage giving the specific tension on the insulating material. Therefore we have $\epsilon = \frac{E}{e\sqrt{3}}$.

If these values are inserted on a curve we see that to each value of ϵ there is a corresponding minimum overall diameter of the cable and that these minima lie on the straight line drawn through the

origin of co-ordinates. The simple relation that exists between r and ϵ is

$$r=\frac{2}{3}\epsilon \cdot \sqrt{3}=\frac{2}{3}\epsilon_1,$$

where ϵ_1 represents the ratio of E to e. The breakdown voltage of impregnated paper can be taken as 20,000 volts per millimetre, if the paper has been thoroughly dried and suitably impregnated. It should, however, be experimentally determined from short lengths of cable, and its value can then be inserted in the above formulæ. Still, a good deal depends on the nature of the surface of the conductor, on the thickness and quality of the paper and on the composition of the impregnating mass; but these factors are left out of account in the present superficial treatment of the subject.

Lately copper cores have been used that are not of a circular section; sometimes they are oval or sector-shaped, the idea being that the overall diameter of the cable is thereby reduced. Sometimes they are semicircular in shape, as in certain kinds of two-core cables. For very high voltages such methods are to be condemned, as the sharp angles have a tendency to raise the potential gradient at these points. The thickness of the insulation must, therefore, be correspondingly raised, and this makes the sector-shaped cable bigger than the round one, This has been often enough shown to be the case under test, and any deviation from the circular form is quite certain to be disadvantageous when high pressures are used. For low pressures the matter is of no importance, seeing that the factor of safety is always very high.

VOLTAGE REGULATION OF GENERATORS.*

BY H. A. LAYCOCK.

Summary.—After discussing voltage regulation generally, the author describes the method of operation and arrangement of the Tirril voltage regulator when used for alternating-current and continuous-current generators.

Various devices have been exploited with a view to obtaining voltage regulation of alternators, but most of them have been based on the principle of the automatic rheostat, which has been unsuccessful due to hunting, and also to the fact that in order for a rheostat to come into operation the voltage must first vary, and of course the moving element being slow, the voltage would vary considerably before the regulating rheostat would operate.

The alternator is a good inherent regulating machine, and is one which is designed at fairly high saturation, with a given excitation it is supposed to regulate within 8 per cent. with a constant speed. In order to obtain the best voltage regulation from an alternator without an automatic regulator the exciter is also run at a high density and is usually compound-wound so that it will either give the same voltage from no-load to full load or will be slightly over-compounded. Probably one of the best voltage-regulating machines was the inductor type alternator, which had a long magnetic path and very high density, in which the time element was six to eight times that of the present revolving-field type of generator. With a non-inductive load this alternator would probably regulate for voltage better than the revolving-field machine, but with an inductive load, which required a much broader range in excitation, the inductor alternator was not satisfactory. The reason this type of alternator was unsatisfactory in regulation was due to the fields requiring a very wide range in excitation, and with an inductive load the excitation was from two to three times that required by the revolving-field type of alternator, and with an automatic regulator, which increases the field excitation according to the variation in load, it was a difficult matter to regulate this type of generator.

* Abstract of a Paper read before the American Institute of Electrical Engineers.

In voltage regulation the exciter is also a very important factor. For example, if an exciter is designed at very high density the time element required to change the voltage from one point to another is so long that the voltage regulation may be materially affected, and, in order to have the best combination for voltage regulation, an alternator should require a range in excitation from no-load to full load (with approximately 80 per cent. power factor) of not more than one to two. The flux densities of the exciters should be fairly low, especially in the fields. The exciter should also have a time element, so that it will be responsive to changes in field excitation to the extent that the voltage will fall, by inserting an external resistance equal to about three times the resistance of the field, from 125 volts to 25 volts in from six to eight seconds. The ideal exciter designed on these lines will also readily give at full field 165 volts, and the increase in field current from 125 volts to 150 volts will not be over 50 per cent.

Before the automatic regulator was perfected the majority of exciters were designed with fairly high densities and very heavy series fields. In some cases the series field equalled 50 per cent. of the total excitation of the exciter, and with an exciter fully loaded it required a very large amount of resistance in the exciter field rheostat to vary the voltage of the exciter to any appreciable extent due to the series field supplying the large amount of excitation and holding up the voltage. In some cases where the series field excitation is about 50 per cent. of the shunt field excitation, the shunt field can be entirely broken under full-load conditions and the voltage would not fall below 60 to 70 volts on 125-volt excitation, but since the adoption of the automatic regulator these conditions have been changed until now the series field excitation does not exceed 30 per cent. of the total shunt excitation and oftentimes it is about 20 per cent., so that very good regulation is obtained by control of the shunt field rheostat.

Automatic Regulators.—The only successful automatic voltage regulator known to the author is that here described, which was

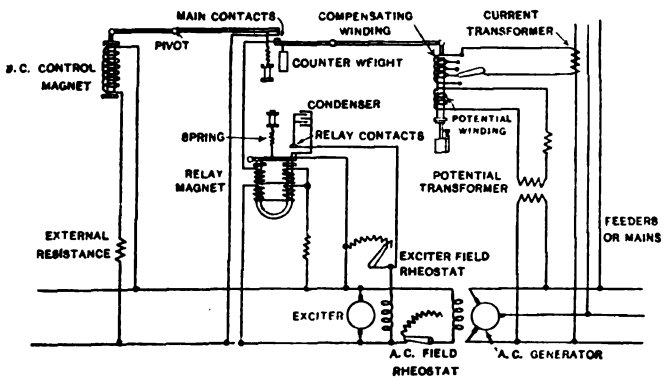

FIG. 1.—CONNECTIONS OF AUTOMATIC REGULATOR.

brought out about 10 years ago and which has been used extensively ever since. This regulator operates on the theory of floating a pair of primary contacts by connecting one coil, which is known as the direct-current control magnet, to the exciter 'bus bars, and is graduated by mounting four springs on the lever connected to this control magnet and supported by a pivot at a proper distance so that this lever operates over the 100 per cent. range in exciter voltage. These springs are so graduated as to pick up a difference of 25 per cent. in voltage; this keeps a constant pressure on the contacts. The alternating-current element of the control magnet, connected to the alternator, is also balanced practically in the same manner except that a counterweight is used instead of springs. It is pivoted in such a manner that with a given voltage—say, 110 volts—a balance is produced in which the contacts supported by the alternating-current lever and the contacts supported by the direct-current lever are at an absolute balance, and with the core of the alternating-current magnet arranged to pull in one direction and the core of the direct-current magnet arranged to pull in the opposite direction this balance is produced in such a manner that the main contacts travel less than $\frac{1}{32}$ in. to obtain a range of 100 per cent. increase in exciter voltage, and the opening at the main contacts in any condition is less than 0·01 in. In addition to the two magnets described above there are also one or more relay magnets, the latter being differentially wound, so that with both windings energised the current is neutralised and the residual is reduced to a minimum, and the operation of the relay is such that it can respond, without any time element, to changes required by the generator. The relay magnet is provided with one or more sets of contacts which are connected across the shunt circuit to the exciter field rheostat, the voltage being reduced

Digitized by Google

first to 65 per cent. below normal, at which point the rheostat is set before the regulator is cut into service. The alternating-current control magnet is also provided with a current winding which is connected to a current transformer in some principal feeder so that the feeder can be overcompounded to take care of the drop in the copper between the central station and centre of distribution. A diagram of the small automatic regulator is shown in Fig. 1. This is a small type of voltage regulator now designed for from one to four exciters, depending upon their capacity. For exciters having larger capacity, Fig. 2 shows diagrammatically the same principle of regulation with the exception of the relay magnet, which is a magnet designed with circular type flat coils but of the differential design, of which from two to 12 sets of relay contacts are employed, depending upon the size and characteristics of the exciters. The diagram shows the connections of two exciters, one set of relay contacts being connected to one exciter, while the second exciter has its field rheostat divided up into two equal ohmic divisions having a set of contacts across each division so that the field discharge is taken up by both sets of contacts equally, and this method can be employed with the present design of voltage regulator up to 24 sets of contacts, having two sets of these relay coils in mulitple controlled by one set of main contacts.

Regulation of Transmission Lines.—The above regulators are designed either to maintain steady 'bus bar voltage or to compensate for non-inductive load through one current transformer. This arrangement does not compensate for an inductive load, and in order to accomplish this result a line drop compensator is employed. Two current transformers are cross-connected in order to deliver the

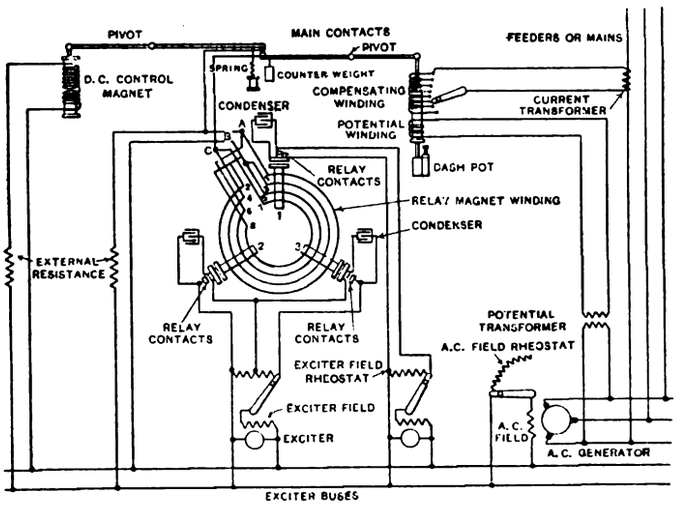

FIG. 2.—CONNECTIONS OF REGULATOR.

proper amount of current to the line drop compensator, which compensator is designed with a reactance coil and resistance coil, the resistance coil being for the non-inductive compensation, and the reactance coil being for the inductive compensation. The current coil of the regulator is omitted with this connection and the compensation is secured by the current flowing either through the reactance or resistance coil of the compensator.

On long transmission lines where a large drop in voltage is experienced from heavy inductive loads it is generally conceded that the adoption of synchronous condensers is an advantage in increasing the output of the central station, and by the application of an automatic voltage regulator with a condenser of the proper size the installation can be made in some remote place along the line where the condenser or regulator needs very little attention and the condensers can be used for automatically compensating for line drop.

The same connections as employed in the alternating-current generator are applicable to synchronous condensers.

The cycle of operation of the ordinary voltage regulator is such that when the main contacts just begin to open the shunt circuit across the exciter field rheostat is opened and the exciter field reduced to a point that without the regulator in service the voltage on the alternator would be about 65 per cent. below normal. The present type of automatic voltage regulator has been so successful because the regulator does not have to wait for the voltage to change, but is operating all the time owing to the fact that the voltage is tending to drop; but the regulator operating at a higher rate of vibration and intermittently short-circuiting and opening the shunt, circuit across the exciter field rheostat makes the time element negligible.

Installations.—As an illustration of the generator capacity for which the automatic voltage regulator is now employed the plant of the Connecticut River Power Co. is cited, in which alternating-current generators aggregating 20,000 kw. are equipped with these regulators. The two 300 kw. 125-volt exciters are driven from vertical turbines and operate in parallel on one voltage regulator. Another application is in the plant of the Ontario Power Co., which delivers 30,000 kw. and contains two 375 kw. exciters equipped with two individual regulators of the eight-relay type.

Voltage Regulation of Direct-Current Generators.—The principle of regulation of the direct-current generator is shown in Fig. 3. The voltage regulator is designed with one main control magnet which is connected permanently to the 'bus bars of the direct-current generators, and has one movable and one stationary core. These cores at a given flux are balanced by the spring, calibrated so as to float them at a certain voltage. The lever supporting the core and spring is equipped with a pair of contacts which operate a relay. For simplicity this relay is shown series wound. The main contacts open and close the winding of the relay which overpowers the spring supporting the armature that carries the relay contacts. The relay contacts are connected across the shunt field rheostat, which is first turned to give about 35 per cent. of the normal voltage that it is desired to maintain, so that when the relay contacts are closed the generator voltage tends to rise until it reaches normal value. The main contacts are opened, thus opening the relay contacts, which tends to reduce the voltage 35 per cent. below normal, but this does not actually happen, as the main contacts, being set for a given voltage and operating at a very high rate of vibration, the voltage is maintained at the predetermined value and is constant under all conditions of load and speed. This was one of the first successful voltage regulators for direct-current generators, but it was limited in capacity to one relay.

As most direct-current generator installations require two or more generators of from 100 kw. to 200 kw. capacity each, a single-relay regulator was found to be too small to handle the field discharge of these large generators. It was therefore necessary to resort to the

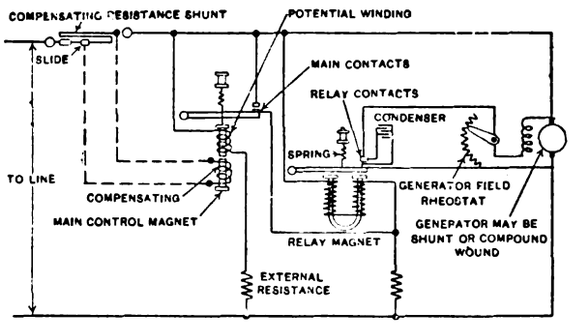

FIG. 3.—CONNECTIONS OF REGULATOR FOR DIRECT-CURRENT GENERATOR

multiple relay type of regulator, which operates on the same principles, but which has a number of relays controlled by one set of main contacts. The multiple relay type of direct-current regulator differs slightly from the alternating-current regulator in the design of the relays, which are differentially wound with parallel conductors so as to neutralise the self-induction of the coils, thus eliminating the sparking at the main contacts. It is impossible to place a condenser section across the main contacts owing to the condenser discharge causing the main contacts to stick, the break not being sufficient to allow the condenser to discharge properly; and if the break is large enough to allow this discharge the regulation will be affected. Condensers are placed across the relay contacts to absorb the arc as these contacts are usually set about $\frac{1}{32}$ in. apart. The connections to the generator field rheostat when multiple relays are used are shown in Fig. 4, in which it will be noted that there are four relays in multiple operating with one set of main contacts.

Another method of regulating direct-current generators is to employ the alternating type of floating contact regulator and separately excite the direct-current generators from an exciter. The direct-current generator in this case virtually becomes an alternating type of generator so far as the principle of regulation is concerned. For Edison three-wire systems, two regulators and two exciters are employed. For large direct-current installations the latter arrangement is very satisfactory as the current to be handled by the regulators is very small and they can also be arranged for over-compounding for line drop by the shunt described above, the current winding opposing the potential winding of each regulator. The exciters for the main generators operate in series the same as the generators themselves.

Special Regulators.—There are numerous applications of voltage regulators which no attempt will be made to describe in this Paper

Digitized by Google

such as regulating alternating-current systems where a storage battery is floating on the exciter bus bars. The method employed is to use a booster with the voltage regulator to boost the exciter voltage to the proper amount. Special regulators are also in use for constant-current work, flywheel equalising sets, and many other special applications.

There is one special appliance in addition to voltage regulators which should be mentioned, and that is an automatic device to be used on an alternating-current system where heavy short-circuits are encountered. If the voltage regulator is employed and a short-circuit is experienced, the action of the regulator will tend to hold the voltage up and, therefore, give the exciter full field. Often in hydro-electric installations when this happens the water-wheel gates are wide open—full excitation is supplied to the exciters and generators—and if the short-circuit is suddenly relieved the voltage is likely to rise above normal value before the excitation can be reduced on the generators and exciters. The time required to reduce the excitation is the time taken by the generators and exciters to demagnetise their fields between maximum full field voltage and the voltage corresponding to the normal load excitation, which may be from two to six seconds. This is augmented by the time required for the water wheels to reduce the speed to normal. This can be overcome by placing overload and high-voltage relays in the transmission line so that should the current increase to a given value the relays will open the connections to the regulator and reduce the voltage to a certain value (to be determined by the operating engineer), and

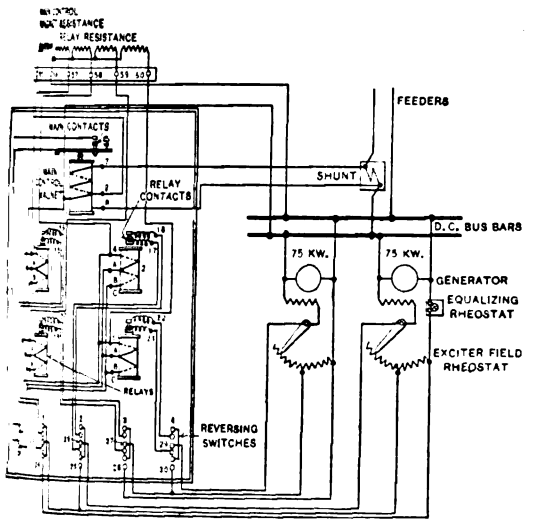

Fig. 4.—Connection of Regulator for Two Direct-Current Generators in Parallel.

when the short-circuit is burned off and the current becomes normal again the relays will close and the regulator will automatically be restored to service. While the above device is not necessary in ordinary central stations it is a very important factor in large hydro-electric installations.

PHOTOGRAPHY AND THE MEASUREMENT OF SURFACE BRIGHTNESS.

In a Paper recently read by Mr. J. S. Dow and Mr. V. H. Mackie before the Royal Photographic Society attention was called to the wide range of brightness with which a photographer has to deal. Incidentally it was also pointed out that the connection between photometry and photography is closer than might be supposed, and that each art can come to the assistance of the other.

Tables have been constructed, both by photographic experts and others interested in school lighting, showing the variation in daylight throughout the year. On this basis Hurter and Driffield, many years ago, devised exposure tables intended to enable photographers to take climatic variations into account. But the drawback to these tables is that although true "in the lump" they may be quite misleading in experience on any actual day. For example, tests by the authors of the illumination between the hours of ten and four on successive days showed that variations of several hundred per cent. were recorded in the intensity of daylight, the lowest value, that of an exceptionally dark period, being about ½ ft.-candle and the highest over 300 ft.-candles. Moreover, in these cases the character of daylight as the day proceeded was entirely different from that indicated by statistics based on long periods of time.

When it is recalled that even greater deviations in brightness are actually met with owing to the variation in daylight in different parts of a room, the varying reflecting power of different objects, &c., the difficulty of obtaining the ideal exposure is obvious. Actinometer readings, again, naturally cannot readily be applied to gain information as to the gradation of tone in an interior, the comparative brightness of near and distant objects, &c., all of which have to be allowed for by more or less rule-of-thumb methods.

The authors therefore suggested the value of actual measurements of the surface brightness of the various objects to be brought out in the field of view, as a means of determining the correct exposure. They showed a series of photographs in which this principle had been applied, the method being to measure the brightness of the chief objects in the field with the Holophane Lumeter illumination photometer.* It will be recalled that this instrument enables the brightness of distant objects to be readily determined, and the authors appear to have used it for studying even such objects as buildings, trees, &c., the brightness of which is largely dependent on the state of the intervening atmosphere.

Among the advantages claimed for such measurements are the speed with which data can be secured and the fact that the instrument enables the relative depth of tone in the different portions of the subject photographed to be studied and recorded in a few seconds. Now it is almost impossible to secure a variation in tone of more than 30 to 1 in the final print, and a record of the degree of shade in the subject thus provides valuable information as to what may be expected when development of the plate takes place, and how far it is possible to approach the actual conditions. The range of surface brightness of objects which are met with in ordinary photography is enormous. Thus, a white surface illuminated by direct bright sunlight may approach 5,000 ft.-candles, but on a dull day may be 1 ft.-candle and less, while dark parts of interiors may yield values of the order of hundredths of a foot-candle. On the other hand, the brightness of actual illuminants is enormous, the electric arc having a brightness equivalent to some millions of foot-candles.

A branch of work in which measurements of surface brightness appear to be specially serviceable is the photography of artificially lighted interiors. Engineers interested in lighting questions have frequently experienced the difficulty of securing photographs of this kind showing, in a proper manner, the distribution of illumination, the actual sources, &c. In this connection Mr. Dow mentioned that Mr. T. E. Ritchie, of the Union Electric Co., had been independently using the Lumeter instrument in this way, and a number of excellent photographs of inverted arc lighting were shown, obtained by Mr. Ritchie in the South Kensington Musuem and elsewhere. A remarkable feature was that the very bright portions of surfaces immediately above the arc were perfectly clear and yet the gradation of tone in the darker parts of the interiors, under arches, &c., was also well represented.

The authors then proceeded to throw on the screen a series of three photographs illustrating the distribution of illumination under a Holophane reflector and a bare lamp respectively. It was pointed out that, in view of the fact that a photographic print will not enable a greater contrast than 30 : 1 to be shown, it was most essential to judge exactly the desirable exposure so as to secure a faithful representation of the exact conditions. This was done by exposing primarily for the surface brightness of white material immediately below the two units compared. Other photographs were also shown of an outdoor subject, and illuminated test charts, &c., in each of which cases the exposure was based on previous experience with the holophane lumeter.

In conclusion, it was suggested that, even in the case of a really expert photographer, the instrument might be of service in affording a record of actual conditions, and that it should also be specially serviceable in teaching photographic principles in research. One question to be born in mind was, of course, the actinic value of different illuminants. It was suggested that although a measure of surface brightness will yield valuable comparative results for the same illuminant, the difference in actinic value must be allowed for when examining interiors lighted by different means. This could be done by adopting certain factors, based on experience, for each illuminant. To illustrate this point a series of photographs were taken of a white card illuminated successively by a carbon filament glow lamp, a metal filament lamp, an incandescent mantle, an arc lamp, a Bastian mercury vapour lamp, a Silica mercury vapour lamp and daylight, the surface brightness as tested by the holophane lumeter instrument being 5-foot-candles and the exposure 1 minute in each case. The negatives were then developed under identical conditions in the same dish, and also fixed in exactly the same manner. As a result it appeared that the exposure for daylight was about right, that the photographs taken by the mercury lamps and the arc lamp were over-

*See The Electrician, Oct. 28, 1910, p. 85.

Digitized by Google

exposed, and that those secured by the light of the glow lamps and the gas mantle were under-exposed. Prints were exhibited showing the gradation of density in the various cases.

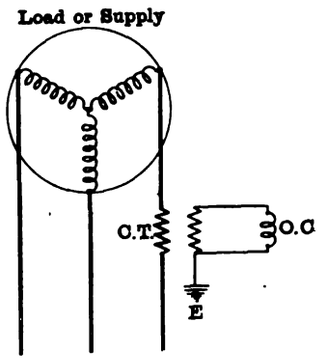
One other question of interest is the applicability of measurements of surface brightness to highly coloured objects, it being recognised that the eye sees such surfaces in a different manner from a photographic plate. This, however, is a difficulty that confronts photographers in any case; it was suggested that it might be mitigated by using a Wratten panchromatic plate and K 3 filter, intended to alter the sensitiveness of the plate in such a manner as to resemble that of the eye much more closely.

Reference was finally made to the value of the Holophane Lumeter instrument for measuring the reflecting power of different materials, stains, solutions, &c., and for studying the opacity of negatives and lantern slides.

PRESENT-DAY METHODS OF PROTECTING HIGH-TENSION SYSTEMS BY MEANS OF AUTOMATIC SWITCHGEAR.

[COMMUNICATED.]

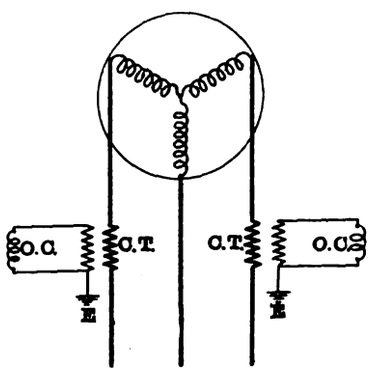
Trouble is often experienced due to the inability correctly to connect together electrically control apparatus after its purchase, and although diagrams are often provided by manufacturers of electrical gear showing the method of connecting their particular gear, the following standard arrangements, it is suggested, may be useful for reference.



C.T. Current transformer. O.C. Oil switch operating coil.

FIG. 1.—OVERLOAD PROTECTION ON BALANCED THREE-PHASE SYSTEM.

The present article is intended to show by the use of diagrams the methods of connecting automatic protective switchgear on high-tension systems of the present day, and deals with apparatus designed to operate in the event of overloads and reversals of power on the systems. The cases taken are those chiefly met with in practice in this country.



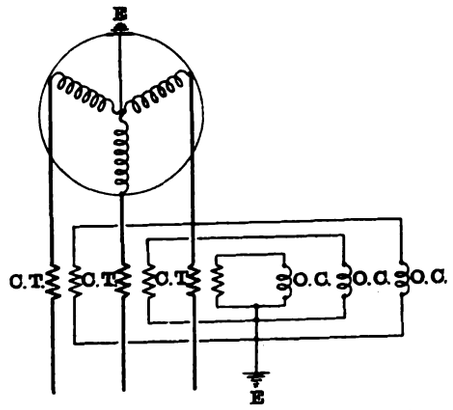
C.T. Current transformer. O.C. Oil switch operating coil.

FIG. 2.—OVERLOAD PROTECTION ON UNBALANCED THREE-PHASE SYSTEM.

Overload Gear.—In Fig. 1 is shown diagrammatically the necessary apparatus for protection against overloads on a three-phase system, where the power is equally balanced in each of the phases. The arrangement necessitates the use of one current transformer connected in one of the phases as shown, with its secondary winding connected to earth; this transformer is coupled with the operating coil of the oil switch, the latter switch not being shown in the diagram. It is immaterial which side of the current transformer secondary winding is connected with earth, although it is well to observe a definite and consistent ruling throughout the practice, and use as the earth terminal, say, the end facing the incoming supply.

Such an arrangement, it will be understood, provides protection against a balanced overload on the system.

Fig. 2 is the case usually met with in practice, viz., the protection against overloads of an unbalanced three-phase system where all the mains are insulated from the mass of our earth. Two current transformers of the same current ratio are necessary to give adequate protection to the system, and these are connected respectively to the oil-switch operating coils, as shown in this diagram. This form of protection is applicable to either the star or delta-connected system where the phases are insulated from earth.

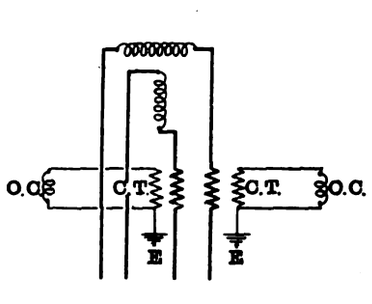


C.T. Current transformer. O.C. Oil switch operating coil.

FIG. 3.—OVERLOAD PROTECTION ON THREE-PHASE SYSTEM WITH NEUTRAL POINT EARTHED.

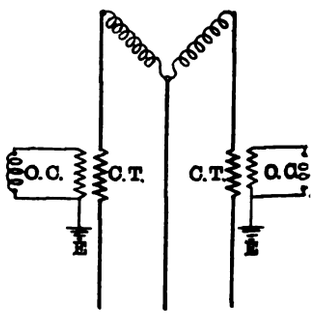
Where the middle point of a star-connected three-phase system is connected to earth, such as is usual on colliery systems, it will be understood that it becomes necessary to provide protection on each of the phases by the use of three transformers connected to three operating coils on the oil switch. Faults to earth, or between the phases, are thus provided for by means of the gear mentioned, connected as shown in Fig. 3.

Overload protection on a two-phase system with four conductors is ensured by the employment of two current transformers connected one in each of the phases, as in Fig. 4. The case can, of course, be treated as two single-phase systems entirely independent of one another.



C.T. Current transformer. O.C. Oil switch operating coil.

FIG. 4.—OVERLOAD PROTECTION ON TWO-PHASE FOUR-WIRE SYSTEM.



C.T. Current transformer. O.C. Oil switch operating coil.

FIG. 5.—OVERLOAD PROTECTION ON TWO-PHASE THREE-WIRE SYSTEM.

As in the two-phase four-wire system, overload protection is maintained on the two-phase three-wire system by means of two current transformers connected in the outer conductors as shown in Fig. 5, and coupled to two operating coils on the main oil switch. In all cases where the line currents are of equal values the current ratios of the operating transformers are the same.

As in the three-phase balanced system the single-phase system requires only one current transformer for its protection,

Digitized by Google

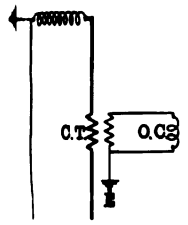
which is connected directly to the operating coil of the oil switch, as shown in Fig. 6.

The method of overload protection still holds good when one side of the system is connected to earth.

Where a relay is introduced in place of the direct-connected operating coil, the connection is as shown in Fig. 7. Such relays are often employed, so that an adjustment of the time operation of the oil switch may be readily made, and also to provide a means whereby direct current can be used for operating the oil switch if desired.

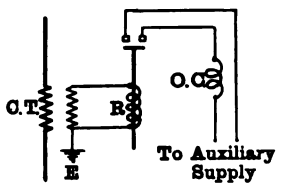
Reverse Power Relays are shown diagrammatically in Figs. 8 to 13 as connected on systems chiefly used in this country.

To protect the balanced three-phase system against a reversal of power, single element protective gear only is necessary. The relay, which consists of a double winding, is supplied by



C.T. Current transformer.
O.C. Oil switch operating coil.

FIG. 6.—OVERLOAD PROTECTION OF INSULATED OR EARTHED SINGLE-PHASE SYSTEM.



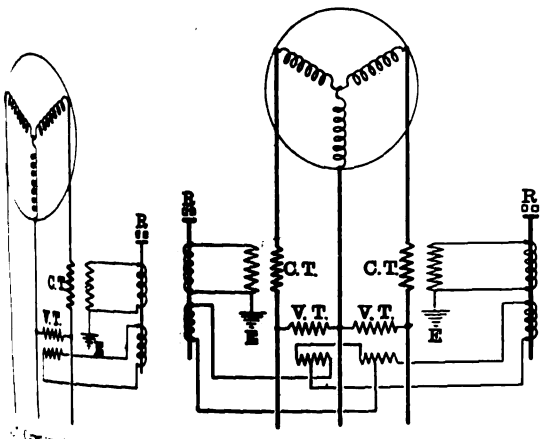
C.T. Current transformer. R Relay.
O.C. Oil switch operating coil.

FIG. 7.—OVERLOAD RELAY IN PLACE OF DIRECT-CONNECTED OPERATING COIL.

means of a current transformer and voltage transformer connected as shown (Fig. 8). Such an arrangement would protect the system against a reversal of power on the assumption that each reverse occurred in each of the phases and, as the system supplies, was balanced.

Proper adjustment of the relay is necessary so that under normal conditions any movement due to electrical influence would be prevented, and that only in the event of a reversal of power in the system would the apparatus fulfil its duties.

It is not intended here to discuss the theory of reverse relays for alternating-current systems, and for further consideration the



C.T. Current transformer. V.T. Voltage transformer. R Relay.

FIG. 8.—REVERSE POWER RELAYS FOR THREE-PHASE BALANCED SYSTEM, STAR OR MESH.

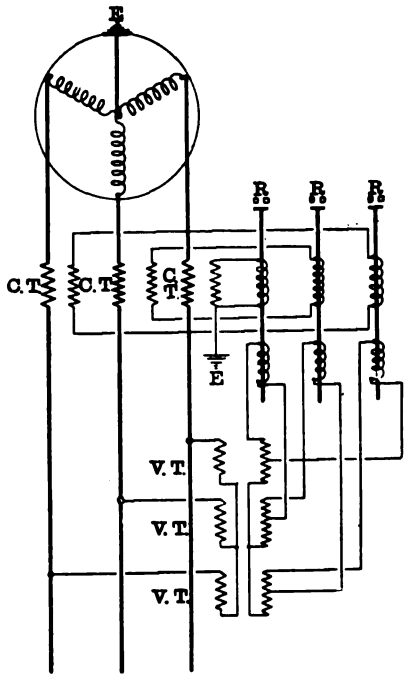
FIG. 9.—REVERSE POWER RELAYS FOR THREE-PHASE UNBALANCED SYSTEM, STAR OR MESH.

reader would refer to the text-book entitled "Electricity Control" by Leonard Andrews, where a simple explanation of the reverse relay is given.

For protecting a three-phase insulated system against independent reversal of power in any phase, it becomes necessary to employ the use of a double set of transformers connected as shown in Fig. 9.

In order to bring the potential and line currents as near as possible into phase in the relay circuit, the voltage transformers are connected to the mid points of their respective secondary windings as shown. This phase correction will be easily understood by reference to an ordinary vector diagram for the three-phase system.

On three-phase systems having the neutral connected to earth it becomes necessary to employ a triple set of gear, the connections being as shown in Fig. 10. The employment of three sets of transformers becomes necessary on account of the

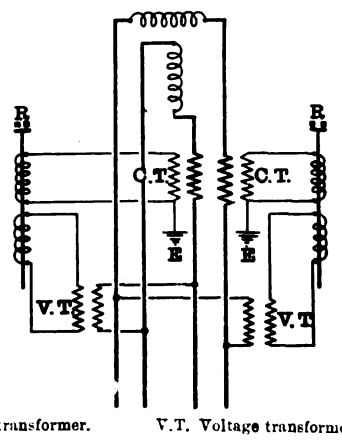


C.T. Current transformer. V.T. Voltage transformer. R Relay.

FIG. 10.—REVERSE POWER RELAYS FOR THREE-PHASE SYSTEM WITH NEUTRAL EARTHED.

possibility of the existence of a different frequency harmonic to the fundamental supply frequency (this, of course, applies when machines are running in parallel). This peculiar phenomenon, as is generally known, can produce circulating currents of considerable value between the phases and earth, which if not guarded against are liable to cause trouble.

By the employment of the transformers shown with the voltage transformers connected in star, trouble that would otherwise be experienced due to the higher frequency harmonics



C.T. Current transformer. V.T. Voltage transformer. R Relay.

FIG. 11.—REVERSE POWER RELAYS ON TWO-PHASE FOUR-WIRE SYSTEM.

is eliminated. As before, phase correction in the relay circuit is obtained by cross connecting the secondary windings of the voltage transformers.

A reference to this diagram will clearly show that a reversal of power on any of the three phases is coped with by the use of this arrangement of protective gear.

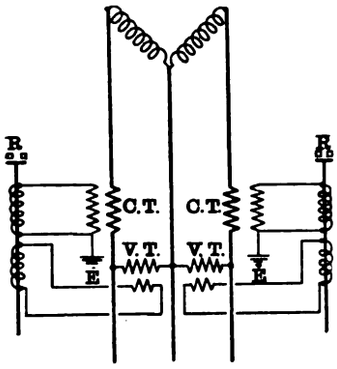
The two-phase three and four-wire systems are protected against power reversal by practically the same method, which consists of connecting in each of the phases one current

Digitized by Google

transformer, and across the phase a voltage transformer interconnected with its relay, as shown (Figs. 11 and 12). The line currents and voltage being presumably in the same phase relationship, correction becomes unnecessary.

Protection is provided in the single-phase system by the use of a single set of gear as in the balanced three-phase system (Fig. 8). The connection shown in Fig. 13 applies equally well for a system where one side is connected with earth.

Conclusion.—It has been intended to show in this article the methods of connecting together the various apparatus dealt with, and not to discriminate between different types and forms of relays or other devices for operating oil switches. More than one form of reverse power relay is in use at the present time, but all types necessitate the use of the operating transformers shown, so that the diagrams will hold good for the different types of apparatus.



C.T. Current transformer.

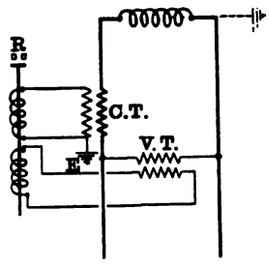
FIG. 12.—REVERSE POWER RELAYS ON TWO-PHASE THREE-WIRE SYSTEM.



C.T. Current transformer.
V.T. Voltage Transformer. R Relay.

FIG. 13.—REVERSE POWER RELAY ON SINGLE-PHASE SYSTEM, INSULATED OR EARTHED.

The question as to whether alternating or direct current should be utilised for operating the oil switches is purely optional, as is also the employment of a three-phase operating transformer in place of three single-phase transformers.

THE HIORTH ELECTRIC STEEL FURNACE.*

BY J. W. RICHARDS.

In this Paper the author describes an improved form of induction furnace due to Hiorth and Söderberg. It is working at Jossingfjord, in Norway, where at least 1,000 water H.P. is available. The furnace is of double-channel induction type, with the primary consisting of four coils connected in series. Fig. 1 shows diagrammatically the electrical principles, E being the steel bath, with its two channels *dd*, *a* the magnetic circuit, *bb* the upper coils, co-extensive with the heating channels, and *cc* the lower coils. The coils *bb* are suspended from pulleys with flexible connections, and, when running, are close to the covers of the channels *dd*, but can be raised about 2 ft. when the covers are to be removed. The coils *bb* are uninsulated, bare copper bars, coiled spirally. The coils *cc* are hollow, water-cooled copper conductors, and in the actual furnace are embedded in the magnesite lining about 16 in. beneath the channels *dd*. The voltage employed on the primary is so low that no particular precautions for insulation are needed, and no one can be seriously hurt by it. The space between the magnet *a* and the furnace wall is a clear foot, which allows the magnets (which weigh several tons) being bolted, firmly fixed to the floor, while the furnace can be tilted for pouring. The central space E is 1 ft. wide in the middle, 2 ft. wide at the sides and nearly 76 in. long from front to back. It furnishes space enough to re-melt ingots or other scrap.

On the occasion of the author's visit the furnace was lined with Veitsch Styrian burnt magnesite, which had been in position for seven weeks, during which it had been occasionally repaired. Norwegian magnesite had been tried and found to crumble badly; it had not been previously properly burnt. The covers were silica slabs, not sufficiently thick, however, properly to protect the melted steel from large radiation losses.

* Abstract of a Paper read before the American Electrochemical Society.

The materials being melted were the purest obtainable Swedish Dannemora pig-iron from the middle bed of the Dannemora ore deposit, and Dannemora Walloon iron, costing, respectively, £6 and £15 per metric ton. These are the identical materials used in Sheffield for crucible melting to produce the best quality of crucible steel. Yellowish-white blast-furnace slag, vitreous and glassy, from the Dannemora furnaces, was being used as a flux, mixed with fluorspar when greater fusibility was desired. The contents of the furnace being 5 tons, 3 tons were poured at a time and 2 tons left in to start the next charge, which then consisted of 3 tons of raw materials. The analyses of the raw materials and of some steels produced from them are given as:

	C.	Si.	Mn.	S.	P.
Dannemora white pig...	3·80	0·310	1·727	0·025	0·020
,, Walloon iron	0·107	0·013	0·068	0·010	0·009
Steel	1·42	0·130	0·322	0·010	0·019
	1·20	0·107	0·269	0·009	0·019
	1·02	0·112	0·301	0·008	0·021
	0·76	0·108	0·253	0·009	0·021
	0·67	0·108	0·288	0·006	0·021

The details of the heat run off when the author was present were as follows —

12:20 p.m. In furnace, 2,775 kg. of previous steel, 1·00 per cent. carbon. Charged 1,000 kg. pig iron and 500 kg. Walloon iron. Current started.
12:30. Current 1,800 A, 273 V, 380 kw., load factor 0·77.
1:30. Current 1,840 A, 273 V, 395 kw., load factor 0·80.
2:0. Current 2,050 A, 265 V, 380 kw., load factor 0·70.
2:30. Charge melted. Average current 380 kw. for 2 hr. 10 min. = 550 kw.-hr. per ton of metal melted.
2:30. Charged 350 kg. pig iron and 1,150 kg. Walloon iron.
3:30. Current 2,275 A, 270 V, 400 kw., load factor 0·65.
4:30. Charge melted. Average current 400 kw. for 2 hours = 530 kw.-hr. per ton of metal melted.

Assuming 300 calories necessary to melt 1 kg. of steel, the thermal efficiency of this melting operation is 55 per cent. and the furnace

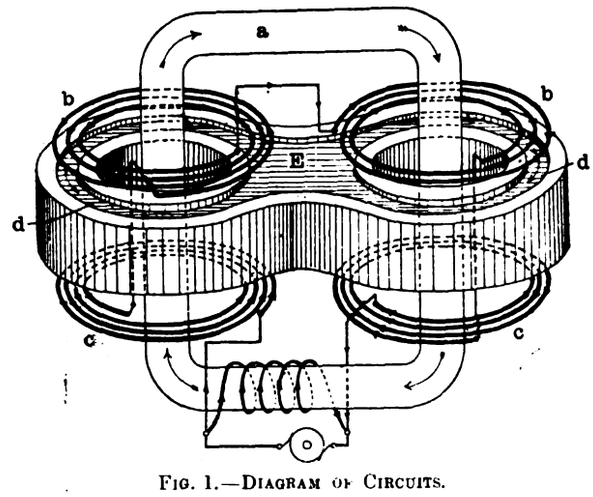


FIG. 1.—DIAGRAM OF CIRCUITS.

radiation loss works out at 180 kw. at this temperature. It was stated that it took about 170 kw. to keep the charge melted when the furnace was heated up over night.

5:30. Current 2,370 A, 265 V, 395 kw., load factor 0·63.
6:0. Current 2,425 A, 278 V, 400 kw., load factor 0·59.
6:15. Current 2,300 A, 280 V, 365 kw., load factor 0·57.

With the metal at casting temperature the current used averaged 395 kw. for six hours, or 790 kw.-hr. per ton of steel. As low a figure as 700 kw.-hr. was reached in this 5-ton furnace on cold materials. During the heat there was added to the bath 35 kg. of 30 per cent. ferro-silicon and 8·7 kg. of 80 per cent. ferro-manganese; while 0·15 kg. of pure aluminium, equal to 0·005 of 1 per cent. of the charge, was added in the ladle.

The steel was poured into 20 cm. square ingots of ½ ton each, and cast beautifully. These ingots were shipped to Sheffield for use in the steel works, and metal from this furnace has already given good service for razors, pocket knives, carvers, chisels, axes, files, reamers, taps, drills, slow-speed turning tools, rock-drills, blacksmiths' tools and engineers' hammers. It sells in competition with crucible steel made from the same materials, the selling price of which is £60 per ton. The labour required on this furnace per 24 hours was one head melter, 1 helper, 1 boy on each of two shifts and 1 ladle man and 1 helper on one shift.

The capacity of the furnace is 12 tons in 24 hours, tapping a 3-ton heat every six hours. When in regular, steady running, 700 kw.-hr. are used per ton of cold charge melted.

Digitized by Google

The principle of the furnace is such that it may be increased almost indefinitely in size; a 50-ton furnace on this design is certainly practicable. In this 5-ton furnace the annular ring channels, 8 in. wide by 18 in. deep, are only filled 8 in. deep with steel, and the narrowness increases the difficulty of working in the slag. Larger furnaces with wider channels will certainly be more free from this arching-over of the slag, because it will fall of its own weight on to the metal.

It is distinctly worth while to remark that the temperature of the steel in the centre compartment was fully as high as in the annular spaces even just before the doors. This shows that, with proper heat-insulating covering over the steel, supplementary heating of the central bath is not a necessity. It appears to the author that the difficulty heretofore met at this point is incidental merely to the smallness of the furnaces, and will disappear as larger furnaces are built.

THE TESTING OF TRANSFORMER IRON.*

BY LANCELOT W. WILD.

When accuracy is the first consideration, transformer iron is doubtless best tested in the form of rings. For routine tests, however, ring specimens are impracticable on account of the cost of winding. For

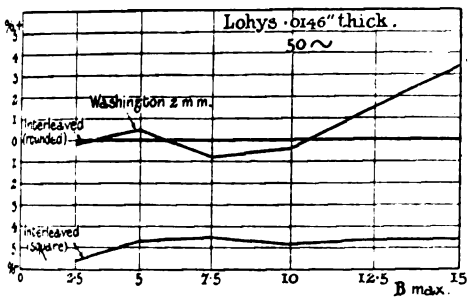

FIG. 1.

everyday testing transformer iron is generally obtained in strips, which are built up to form some form of magnetic square, the strips being threaded into coils ready wound, and fixed to a base-board.

The "interleaved butt-joint system with square corners" has been very largely employed. In this the strips are built up with butt joints differently disposed in alternate layers, so that the joint in one layer is covered by continuous iron in the next. In the system employed at the National Bureau of Standards, Washington, which may be called the Washington system,† the strips of iron are interleaved with strips of paper or other suitable insulating material of the same thickness as the iron. They are then made up into four bundles, which are wound round with tape and inserted into the coils. Corner-pieces are then cut and bent, each to a different length, and these are inserted between the ends of the strips. A

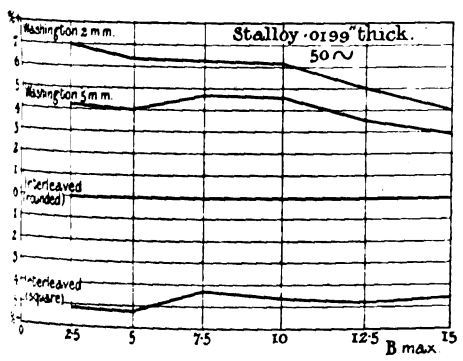

FIG. 2.

clamp is finally placed at each corner, and is tightened up so that the strips and corner-pieces are held fast together. The two chief objections to the interleaved system are, first, that the difference between the longest and shortest path presented to the flux is great; and, secondly, at the corners the cross-sectional area is increased to above the normal. At low densities the flux will tend to crowd into the shortest path, and this should increase the specific loss as a whole. At high densities the decreasing permeability will tend to cause the flux to spread out more, and at very high densities, if there is no magnetic leakage, the results obtained will tend to come out correctly.

The objection to the interleaved system can partly be overcome by rounding the corners. This renders the cross-section constant at all points of the circuit. The fault that naturally occurs to one with regard to the Washington system is that the cutting and bending of the corner-pieces is likely so to increase hysteresis locally as to vitiate the total measurement. There is also the practical consideration that the operation of making and fitting the corner-pieces takes a considerable amount of time.

In order to arrive at a general idea of the magnitude of the errors involved, the author has made comparative tests on four specimens, employing all three systems, the strips used measuring 10 × 2 in. The specimens were of Lohys and Stalloy. The results are set out in tables and diagrams in the Paper. Two diagrams showing the percentage differences are given herewith (Figs. 1 and 2).

Conclusions.—The author says there appear to be two general conclusions that may be arrived at from these tests with a considerable degree of certainty. Firstly, the Washington method is quite unsuitable for Stalloy, and is of rather doubtful utility for Lohys. Secondly, if it should be decided that the interleaved method with rounded corners is the most accurate, it is hardly necessary to trouble about cutting the corners round. If the amount of waste material at the corners is deducted from the gross weight, the results obtained will not differ by more than 1 per cent. from the results that would have been obtained had the corners been rounded.

It appears to the author that the interleaved method is still the best method of testing transformer iron available. It is generally agreed that if accurate results are to be obtained the strips must be annealed after being cut, and this can only properly be done by the manufacturer. There is no special virtue, then, in using wide strips.

MEASUREMENTS OF INTRINSIC BRIGHTNESS BY A NEW METHOD.*

BY H. E. IVES AND M. LUCKIESH.

The apparatus here described lends itself to the making of measurements of intrinsic brightness in a more direct manner than any hitherto known to the writers. The instrument used is a modification of the Holborn-Kurlbaum optical pyrometer. In this latter instrument the furnace or surface the temperature of which is to be measured is viewed directly, while between the eye and the object is placed an incandescent lamp filament. The current in the filament is varied until the filament becomes invisible—that is, until its brightness is the same as that of the background. A previous calibration of the filament makes it possible to state this intrinsic brightness in terms of "black-body temperature." A temperature measurement with this instrument might, however, be expressed in terms of brightness per unit of area by means of the data of Nernst† on the candle-power per square millimetre of a black body at various temperatures.

In attempting to apply this method of measuring intrinsic brightness to the measurement of illuminants the usual conditions are reversed. That is, instead of having a background of large extent, against which the auxiliary lamp filament may be matched, the surfaces to be measured are often of very small dimensions. For instance, an incandescent lamp filament is so small that the attempt to match one with the brightness of another filament crossing it is altogether impracticable. The difficulties have been overcome by using as background the image of a Nernst glower. In the first place, the glower happens to have a higher intrinsic brightness than any of the incandescent filaments. In the second place, since it is operated in the air, and not in a bulb, an image may be formed by a lens without distortion. In the third place, the ordinary commercial glower is large enough so that only a few-fold magnification is necessary.

A few words are necessary in regard to the use of an image as a background. It follows from geometrical optics that the intrinsic brightness of an image in space, as viewed from the side away from the lens forming it, is equal to the brightness of the original source, provided the beam of light entirely fills the pupil of the eye or the aperture of the telescope with which the image is viewed. Consequently, an image of any convenient size may be used, and it may be focussed in any plane desired, such, for instance, as that of a lamp filament in a bulb. In the latter case the relative position of filament, lens and bulb is such that no troublesome distortion is introduced by the glass of the bulb. The absorption of the lens has, of course, to be taken into account.

* Abstract of an article in the "Electrical World."

† "Phys. Zeit.," June 1, 1906.

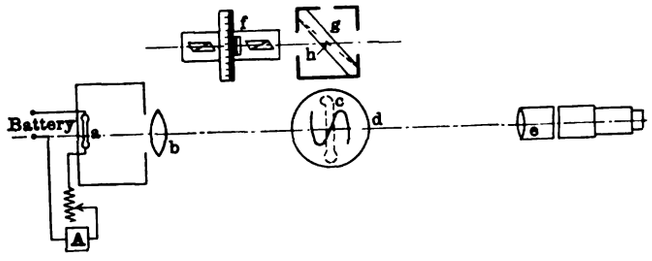
A plan of the apparatus is shown in the accompanying diagram, where *a* is the Nernst glower enclosed in a tin box to avoid draughts. For this work a direct-current 0·6 ampere glower was used, without the heating coil. Current was read by the ammeter A; *b* is the lens, *c* is the enlarged image of the glower in the plane of *d*, the incandescent lamp to be measured, and *e* is the observing telescope.

In order to make measurements it is obviously necessary to vary the brightness of the Nernst image and to know the values of this brightness. Several means of changing the candle-power of the Nernst were tried, and finally two were employed, each for a different range. In measuring the incandescent lamps it was found most satisfactory to change the Nernst by varying the current through it. Separate photometer measurements gave the relationship between current and brightness in the glower. This means of varying the brightness could not be used for low values (below 200 c.p. per square inch) owing to the failure of the glower to operate. For other illuminants of lower intrinsic brightness a pair of Nicol prisms, *f*, were inserted. Their angle of rotation relative to each other could be read; when a setting was made each side of the extinction point (θ_1 and θ_2) the brightness of the glower image was $a \sin^2 \frac{\theta_2 - \theta_1}{2}$, where *a* is the transmission of the Nicol prisms at their point of maximum transmission. This formed a very satisfactory method for varying the brightness of the background, and would have been preferable throughout were it not that the absorption of the Nicol prisms reduces the background intensity below the value necessary for matching the lamp filaments at their normal operation.

For the measurement of flames and other illuminants of an extended character it was necessary to introduce an auxiliary device. A thin, reflecting filament was made, consisting of a ½ mm. strip of silver, *h*, chemically deposited on the back of a 7 deg. prism. Against this a second prism was cemented with Canada balsam, so that the outer faces of the prisms were parallel, but at an angle with the silver strip. This compound prism was enclosed in a small box, *g*, with



PLAN OF APPARATUS FOR MEASURING BRIGHTNESS OF LIGHT.

front, back and a narrow side opening. By this means all reflections except those from the silver strip were invisible at the telescope. Portions of flames reflected in this strip appear very much like the lamp filaments and disappear very satisfactorily against the background.

Some of the values obtained in the present investigation are given in the accompanying table, together with some values given by Barrows for comparison. The incandescent lamp values given refer to the brightness inside the bulb; they will be about 10 per cent. less as ordinarily viewed.

Type of lamp.	Barrows. C.p. per sq. in.	Ives & Luckiesh. C.p. per sq. in.
Crater, carbon arc	200,000	84,000
Flaming arc	5,000	...
Nernst glower (115-volt 6-ampere d.c.)	...	3,010
Tungsten, 1·25 watts per candle-power	1,000	1,060
Tantalum, 2 watts per candle-power	750	580
Carbon, 3·5 watts per candle-power	375	400
Carbon, 4 watts per candle-power	300	325
Enclosed carbon arc (direct-current)	100–500	...
Welsbach mantle	20–25	31·0
Cooper-Hewitt mercury vapour	16·7	14·9
Candle flame	3–4	...
Gas flame (fishtail)	3–8	2·7
Frosted incandescent lamp	4–8	...
Tip of 25-watt frosted tungsten	...	1·67
Side of ditto	...	6·00
Moore carbon-dioxide tube	0·6	...

Some improvements in the apparatus might be made as a result of experience with these measurements. Chief among these would be the use of some other background. The direct-current Nernst glower proved somewhat fragile. A thick tungsten filament in a fairly flat and uniform or large diameter bulb would be preferable. In the event of using a filament of this type a purely substitution method would be advisable, referring all measurements to a filament of known brightness, itself matched against the special tungsten background.

These modifications of the procedure would be well to follow were intrinsic brightness measurements found of such use in any photometric method as to make convenience in obtaining them of practical importance. As a matter of fact, the present apparatus was devised to test the possibility of rating incandescent lamps at a uniform specific consumption by setting them at the same intrinsic brightness. The method has been found good, but unfortunately too good for commercial incandescent lamps. These vary from filament to filament and from point to point on one filament by an amount corresponding to several volts. Further difficulties might have developed due to differences in vacuum, &c.

ON RESISTANCES WITH CURRENT AND POTENTIAL TERMINALS.

(*Concluded from page 14.*)

BY G. F. C. SEARLE, M.A., F.R.S.

Summary.—Although conducting systems with current and potential terminals have been in use for many years, the general theory of conduction through such systems has received little attention. The usual proof of the important theorem that current and potential terminals may be interchanged without affecting the P.D. on the main resistance involves the condition that the whole of any one junction is at the same potential. This condition is approximately satisfied in the case of a network of fine wires, but not in a "low resistance" or "shunt." In dealing with such a system we need a proof of the reciprocal relation which shall be independent of the form of the system. Helmholtz has given such a proof, and a simple, direct one is here given due to Heaviside. Dr. Bromwich, employing Green's theorem, also gives a solution. Useful information regarding the properties of conducting systems with three and four terminals is obtained, and it is shown that a triangle of resistances may be replaced for all purposes by a three-rayed star of resistances. In the case of a four-terminal resistance we can construct even low resistance systems such that the want of infinite conductivity at the junctions can produce no sensible error. The discussion of the design of such resistances shows the great advantage of connecting each current and each potential terminal to the main resistance by a rod or wire, the length of such being at least three times its greatest width. The resistance of such a system is very definite. In the case of low resistances capable of carrying currents of the order of 1,000 amperes, slight changes in the connections at the terminal lugs have been found to produce appreciable changes in the P.D. on the main resistance. These defects are easily remedied. Potential "tongues" in sheet resistances are shown to be an advantage. For the comparison of four-terminal resistances with other resistances five methods are discussed, the most important of them being the Thomson bridge, which possesses an advantage not previously realised.

§ 25. *Comparisons of Four-terminal Resistances with Other Resistances.*—We now proceed to discuss some methods of comparing the four-terminal resistance [CD . AB] or [AB . CD] for any given system having current terminals AB and potential terminals C D with other resistances. The resistance [CD . AB] can be compared with the four-terminal resistance [C′D′ . A′B′] of a standard system by means of potentiometer methods. But these methods assume the constancy of currents of 100 amperes or more in the case of very low resistances, and thus cannot be expected to yield as accurate results as suitable Wheatstone bridge methods, in which no assumption is made as to the constancy of the current. For commercial purposes the potentiometer methods are satisfactory, but they will be passed by here in favour of the bridge methods.

The methods discussed below are applicable to *any* given system and do not require for their theoretical validity that the resistance [BD . AC] should vanish. In some cases, as, for instance, that of a mercury standard of resistance with current and potential terminals, the resistance [BD . AC] is so exceedingly small that it may be safely treated as if it were accurately zero. In these cases the system may be replaced by a five-wire model, as in § 17, and then a number of methods take simple forms. But it must not be assumed without special examination that the formulæ which are valid when [BD . AC] is zero can be applied to cases in which [BD . AC] is not zero. The methods given below are applicable to systems of any form.

§ 26. *First Method.*—The system for which the resistance [CD . AB] is to be found is associated, as in Fig. 21, with three

Digitized by Google

resistances, P, Q, S, without potential terminals, and an additional resistance, T, is included between the points A and L. The battery is joined to N and L, and the galvanometer joins M and C or M and D. By the reciprocal relation of §23 we may, as far as theory goes, interchange the battery and the galvanometer. In practice that arrangement should be chosen which gives the greatest sensitiveness.

Let the resistance [CD . AB] be denoted by R, let [AC . AB] be denoted by X and [DB . AB] by Y. Then when a current of 1 ampere flows from L to N through B, $V_A - V_C = X$ volts, $V_C - V_D = R$ volts, and $V_D - V_B = Y$ volts.

The galvanometer is first joined to M and C, and the bridge is balanced by adjusting T or S or both. Let the balance values be T_1 and S_1. Let u_1 be the current in the branch LBN and v_1 that in LMN. Then, since C and M are at the same potential, we have

$$(T_1+X)u_1 = Pv_1,$$
$$(R+S_1+Y)u_1 = Qv_1.$$

Hence,

$$Y - \frac{QX}{P} = \frac{QT_1}{P} - R - S_1 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The galvanometer is now joined to M and D, and the bridge is again balanced by adjusting T or S or both. Let the balance

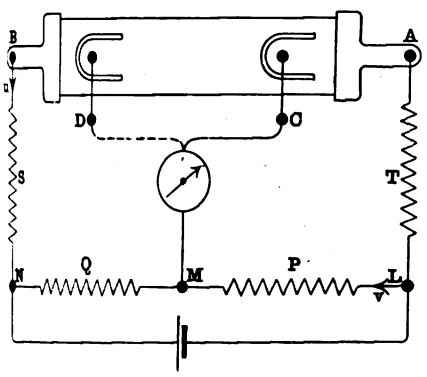


FIG. 21.

values be T_2, S_2, and let the currents now be u_2, v_2. Then, since M and D are at the same potential,

$$(T_2+X+R)u_2 = Pv_2,$$
$$(S_2+Y)u_2 = Qv_2.$$

Hence,

$$Y - \frac{QX}{P} = \frac{Q(T_2+R)}{P} - S_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

By subtracting (1) from (2) we obtain

$$R = \frac{P(S_2-S_1)+Q(T_1-T_2)}{P+Q} \quad . \quad . \quad . \quad . \quad (3)$$

If T is kept constant, we have

$$R = \frac{P(S_2-S_1)}{P+Q}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and if S is kept constant,

$$R = \frac{Q(T_1-T_2)}{P+Q} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Hence (4) or (5) we require the absolute value of $S_2 - S_1$, or of $T_1 - T_2$, and of the ratio P/Q.

If equation (4) be used, the measurements are easily made by using a resistance box furnished with proportional arms. These arms carry the resistances P and Q, and the remainder of the box carries S. The coil T may be any coil whose resistance is sufficiently great to allow a balance to be obtained when the galvanometer is connected to M and C. The fine adjustment of value BN may be made by shunting.

If the resistances P and Q be equal, we have by (4)

$$R = \tfrac{1}{2}(S_2 - S_1).$$

Hence if we make S_1 zero by making B coincide with N in the first adjustment, which is then made by varying T, the value of R is $\frac{1}{2}S_2$—i.e., R will be half the resistance which must be inserted between B and N in the second adjustment. In this way a four-terminal resistance, R, of nominally 1 ohm can be compared with a coil, S_2, of nominally 2 ohms resistance. If the 2 ohm coil be greater than 2R the exact balance can be obtained by shunting the 2-ohm coil. If, on the other hand, the 2-ohm coil be less than 2R, the two potentials C D are connected by a shunt wire of such resistance as to make the shunted value of 2R less than the 2-ohm coil; the second adjustment can then be made by shunting the 2-ohm coil. The true value of R can then be deduced from the shunted value by equation (6) of § 23. An alternative method is to use (3), and to make $S_2 - S_1$ nominally 2 ohms, while the fine adjustments are made by varying T by shunting.

The connections may be made by mercury cups formed in stout blocks of copper. For the most precise work some allowance must be made, where necessary, for the resistance between two Mercury cups in the same block; in the blocks used at the National Physical Laboratory this resistance is about 3×10^{-6} ohms.

§ 27. *Second Method.*—In the last method two adjustments of a Wheatstone bridge are necessary; in the present method

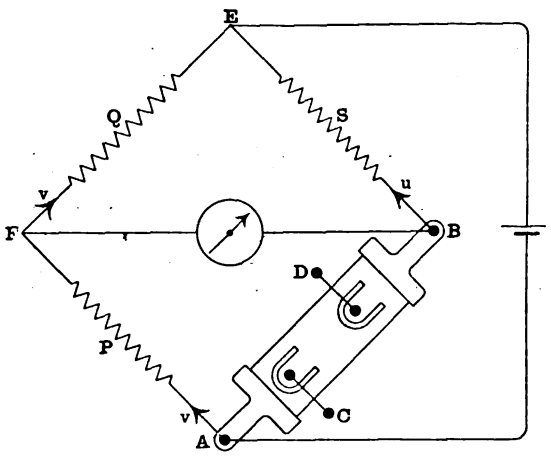

FIG. 22.

three adjustments are required. The system, having current terminals A B and potential terminals C D, is associated with three other resistances P, Q, S, as in Fig. 22. In the first adjustment the battery is joined to E and A, and the galvanometer to F and B, and P_1, Q_1, S_1 are the values required for a balance. Then

$$[AB] = P_1S_1/Q_1.$$

Let [CD . AB] be denoted by R. Then, since [AB] = [AB . AB],

$$[AB] = [AC . AB] + [CD . AB] + [DB . AB]$$
$$= R + [AC . AB] + [DB . AB].$$

For convenience we shall denote [AC . AB] by X and [DB . AB] by Y, and P_1S_1/Q_1 by R_1. Then

$$R + X + Y = R_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

For the second adjustment the battery is joined to E and A and the galvanometer to F and D, and the balancing resistances are P_2, Q_2, S_2; we denote P_2S_2/Q_2 by R_2. Then, if u and v be the currents in ABE, AFE, we have

$$Q_2v = [DB . AB]u + S_2u = Yu + S_2u,$$
$$P_2v = [AD . AB]u = [CD . AB]u + [AC . AB]u = Ru + Xu.$$

Hence, by eliminating u/v,

$$R + X - YP_2/Q_2 = R_2. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

For the third adjustment the battery is joined to E and C and the galvanometer to F and B. The balancing resistances are P_3, Q_3, S_3, and P_3S_3/Q_3 is denoted by R_3. Then

$$Q_3v = S_3u.$$

Equating to zero the P.D. between F and B for the branch BAF, we have

$$P_3v + [BA . CA]v + [BA . CB]u = 0,$$

or

$$P_3v + Xv = [CB . AB]u = [CD . AB]u + Yu = Ru + Yu.$$

Hence

$$R - XS_3/Q_3 + Y = R_3. \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Digitized by Google

From (1), (2) and (3) we can find R, X, and Y. From (1) and (3)

$$X=\frac{(R_1-R_3)}{1+S_3/Q_3}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and from (1) and (2)

$$Y=\frac{R_1-R_2}{1+P_2/Q_2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Hence, by (1),

$$R=R_1-X-Y=R_1-\frac{R_1-R_3}{1+S_3/Q_3}-\frac{R_1-R_2}{1+P_2/Q_2}. \quad . \quad . \quad (6)$$

This method is well adapted for measurements on standard 1-ohm coils having current and potential terminals. In these coils the potential and current terminals at each end of the system are close together on a thick copper conductor, and thus R_1-R_3 and R_1-R_2 will be small. The small changes which are required to produce a balance in the three positions can be very accurately made by shunting one out of P, Q and S. It will be seen that the resistances are permanently connected at A, B, E, F, and thus all variable contact resistances are eliminated.

It will be seen that equations (1), (2) and (3) are exactly those which we should have obtained if the system A, B, C, D had been of the form shown in Fig. 23; here H K are joints of perfect conductivity and AH=X, HK=R and KB=Y. But the model in Fig. 23 *cannot* replace the actual system for *all* purposes, unless it happens that [AC . BD]=0 for the system itself. In the determination of R or [AB . CD] by the present method we are, however, only concerned with the three resistances R=[AB . CD], X=[AC . AB] and Y=[DB . AB], and thus the actual system may be replaced by *any* model which has the same values of these three resistances as the system itself has.

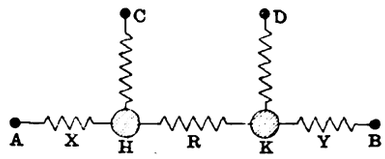

Fig. 23.

The model of Fig. 23 is not the only one which may be substituted for the actual system *for the purpose of the present measurement*. If we express R, X, Y in terms of the resistances of the eight-wire model of Fig. 7, we obtain

$$R=[AB\,.\,CD]=r_{13}-r_{23}=p^2/(p+q),$$
$$X=[AC\,.\,AB]=r_{11}-r_{13}-r_{12}+r_{23}=a+pq/(p+q),$$
$$Y=[DB\,.\,AB]=r_{22}-r_{12}=b+pq/(p+q).$$

If we select any value for q we can find from these equations the values of p, a, b in terms of R, X, Y, q, and thus we can make as many models as we please. But each of these will only serve to define [AB . CD], [AC . AB] and [DB . AB], and *cannot be used for any other purpose*.

§ 28. *Third Method.*—This method depends upon the results (8) and (9) of § 23. Let $[AB]_Q$ be the resistance between A and B when C and D are joined by a wire of resistance, Q, while [AB] is the value when Q is absent. Let $[CD]_P$ be the resistance between C and D when A and B are joined by a wire of resistance, P, which [CD] is the value when P is absent. Then,

$$[AB\,.\,CD]^2=\{[AB]-[AB]_Q\}\{Q+[CD]\}, \quad . \quad . \quad . \quad (1)$$
$$[AB\,.\,CD]^2=\{[CD]-[CD]_P\}\{P+[AB]\}. \quad . \quad . \quad . \quad (2)$$

It is convenient to attach to the four terminals A, B, C, D (Fig. 24) four connecting wires AE, BF, CG, DH, the lengths of these wires being sufficient to allow them to be connected to the proper points of the resistance box or other form of the Wheatstone bridge which may be employed. The connections at A, B, C, D must be carefully made, and must remain undisturbed during the series of measurements. If due regard has been paid to the design of the system A, B, C, D we may write

$$[AB\,.\,CD]=[EF\,.\,GH],\quad [BC\,.\,AD]=[FG\,.\,EH],$$
$$[CA\,.\,BD]=[GE\,.\,FH],$$

and hence we may substitute the points E, F, G, H for A, B, C, D as far as the three four-terminal resistances are concerned.

The points E and F are connected to the Wheatstone bridge and the resistance [EF] is found. The points G H are then connected by a good short-circuiting key, and the new resistance $[EF]_0$ is measured. If CG+DH=Q, we have

$$[AB]-[AB]_Q=[EF]-[EF]_0.$$

Since Q+[CD] is the resistance between G and H when E and F are not connected, Q+[CD] may be denoted by [GH]. Thus, by (1)

$$[AB\,.\,CD]^2=\{[EF]-[EF]_0\}[GH].$$

The *sign* to be given to [AB . CD] depends upon which of the two potential terminals is denoted by C.

If $[GH]_0$ be the resistance between G and H when E and F are connected by a short-circuiting key, we have, by (2)

$$[AB\,.\,CD]^2=\{[GH]-[GH]_0\}[EF].$$

The method is not well adapted for cases in which [AB . CD] is very small, on account of the impossibility of securing invariable contact resistances at EF and GH.

§ 29. *Fourth Method.*—This method depends upon the result obtained in § 13.

$$[AB\,.\,CD]=\tfrac{1}{2}\{[AD]+[BC]-[AC]-[BD]\}.$$

Four connecting wires AE, BF, CG, DH are joined to this system as in Fig. 24. If the system is properly designed, [EF . GH]=[AB . CD]. In this case

$$[AB\,.\,CD]=\tfrac{1}{2}\{[EH]+[FG]-[EG]-[FH]\}. \quad . \quad . \quad (1)$$

Thus, [AB . CD] can be found by measuring the four resistances on the right side of (1). If the two additional resistances

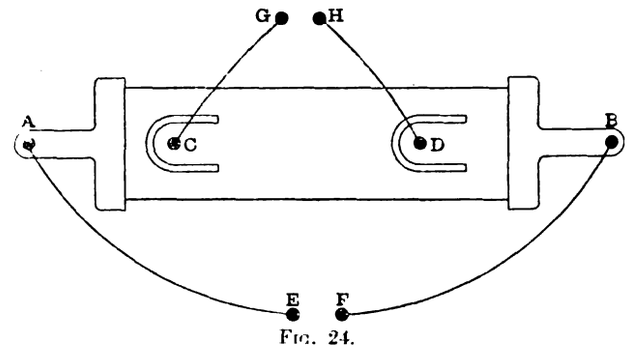

Fig. 24.

[EF] and [GH] are determined the whole of the six two-terminal resistances for the system EFGH are known, and hence [BC . AD] and [CA . BD] can be found. The resistances of the four wires AE, BF, CG, DH can be measured, and so the six resistances AB, AC, AD, BC, BD, CD can be found. All the three-terminal resistances for the system can then be calculated. Though this method gives more information than the others, the large number of variable contacts involved tends to make it less accurate, unless the six resistances AB, AC .... are large. . . .

§ 30. *The Thomson Bridge.*—In the previous methods the four-terminal resistance [AB . CD] of a system ABCD is compared with a number of two-terminal resistances. In Lord Kelvin's method a second system, EFGH, is employed, and the ratio of [AB . CD] to [EF . GH] is determined by the aid of a number of two-terminal resistances. The method has the great advantage that the inevitable contact resistances affect only coils of considerable resistance, and thus the method may be used for accurate comparisons of four-terminal resistances as low as 0·00001 ohm.

When the systems are such that [AC . BD]=0 and [EG . HF]=0 each system can be replaced by the simple five-wire model discussed in § 17, and the derivation of the necessary formulæ is very easy. It has been generally assumed that the systems occurring in practice can be replaced by these simple models, and the formulæ have been obtained on that assumption. In some cases the special condition is exceedingly nearly satisfied, but in the case of very low resistances the special condition is only approximately satisfied. Since the Thomson bridge is the best method of comparing these very low resistances it becomes essential to obtain the accurate formulæ which apply to the general case in which [AC . BD] and [EG . HF] do not vanish.

Digitized by Google

The arrangements for carrying out the method are shown in Fig. 25. One of the systems has AB for current terminals and CD for potential terminals. Its four-terminal resistance AB (CD) or [CD . AB] will be denoted by P. The other system has EF for current terminals and GH for potential terminals, and [EF . GH] or [GH . EF] will be denoted by Q. The two systems are associated with two main resistances KD = R, KH = S, and with two auxiliary resistances LC = U, LG = V. The terminals AE are joined by a connector AOE of small resistance, the smaller the better. It is convenient to select some definite point on AE and to denote it by O.

We shall now investigate the relation which exists among the various resistances, when the galvanometer indicates no current. Let the battery current $x+y+z$ so distribute itself that x flows along DKH through R and S, y along CLG through U and V, and z along the connector AOE. Since there is a balance, the difference of potential between D and K is equal to that between D and L, and the difference of potential between K and H is equal to that between L and H. Further, the difference of potential between L and O by the path LCO is equal to that by the path LGO. Expressing these three conditions in symbols, we obtain the three equations

$$Rx=[DL\,.\,BD]x+[DL\,.\,BL]y+[DL\,.\,BO]z,$$
$$Sx=[HL\,.\,FH]x+[HL\,.\,FL]y+[HL\,.\,FO]z,$$
$$0=[LO\,.\,BD]x+[LO\,.\,BL]y+[LO\,.\,BO]z=[LO\,.\,HF]x+[LO\,.\,LF]y+[LO\,.\,OF]z.$$

When the current and potential terminals are properly selected, we may write

$$[DL\,.\,BO]=[DC\,.\,BA]=[CD\,.\,AB]=P,$$
$$[HL\,.\,FO]=[HG\,.\,FE]=[GH\,.\,EF]=Q.$$

We shall employ the following abbreviations :—

$$R=[DL\,.\,BD]=R+[CD\,.\,BD]=R',$$
$$S=[HL\,.\,FH]=S+[GH\,.\,FH]=S',$$
$$U=[DC\,.\,AC]=U',\quad V+[HG\,.\,EG]=V',$$
$$[LO\,.\,BO]+[OL\,.\,OF]=[CO\,.\,BO]+[OG\,.\,OF]=N,$$
$$[DL\,.\,BD]=[OL\,.\,BD]=W_P,\quad [EG\,.\,FH]=[OL\,.\,FH]=W_Q,$$
$$W_P+W_Q=W.$$

Then we have

$$[DL\,.\,BL]=U=[DC\,.\,BC]=U+[DC\,.\,BA]+[DC\,.\,AC]=U'+P$$
$$[HL\,.\,FL]=V=[HG\,.\,FG]=V+[HG\,.\,FE]+[HG\,.\,EG]=V'+Q,$$
$$[LO\,.\,LF]=U+[CA\,.\,CB]+V+[GE\,.\,GF],$$
$$=U+[BD\,.\,AC]+[DC\,.\,AC]+V+[EG\,.\,FH]+[HG\,.\,EG],$$
$$=U'+W_P+V'+W_Q=U'+V'+W.$$

By use of the abbreviations the three equations for x, y, z become

$$R'x-(U'+P)y-Pz=0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$
$$S'x-(V'+Q)y-Qz=0. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$
$$Wx-(U'+V'+W)y-Nz=0. \quad . \quad . \quad . \quad . \quad (3)$$

The relation existing between the resistances when no current passes through the galvanometer is found by eliminating x, y, z from these equations. The relation can be expressed in two forms. To obtain the first form we write

$$U'-P=X,\quad V'+Q=Y,\quad U'+V'+W=M.$$

Then we have

$$PS'(M-YW)-Q(MR'+XW)+N(S'X-R'Y)=0.$$

Or

$$PS'\left\{M+YW+W\left(\frac{S'X}{R'}-Y\right)\right\}-N(S'X-R'Y),$$
$$\frac{P}{Q}=\frac{R'}{S'}-\frac{Y}{Q}\cdot\frac{N-QW/S'\left(X\quad R'\right)}{M+YW/S'\left(Y\quad S'\right)}. \quad . \quad . \quad . \quad (4)$$

The ratio X/Y can be found by a second adjustment of the resistances. The connector AOE is removed, and R and S are adjusted to the values R_0 and S_0, the corresponding values of R' and S' being R_0' and S_0'. The resistances U and V remain unchanged and thus X and Y are unchanged. Since the current now flows, zero the equations for x and y are

$$R_0'x=Xy,\quad S_0'x=Yy,$$
$$X/Y=R_0'/S_0'.$$

The general condition for a balance when the connector AOE is in place can then be written

$$\frac{P}{Q}=\frac{R'}{S'}-\frac{Y}{Q}\cdot\frac{N-QW/S'\left(R_0'\quad R'\right)}{M+YW/S'\left(S_0'\quad S'\right)}. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

If the four resistances R, S, U, V can be so adjusted that the removal of the connector does not disturb the balance, then $R_0'/S_0'=R'/S'$. The equation then takes the simple form

$$P/Q=R'/S'. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The quantity N depends upon the resistance of the connector AOE, and cannot be made to vanish. The presence of W expresses the fact that the two systems cannot be replaced by two five-wire models, since W does not vanish unless the systems can be so replaced ; we need not consider the special case in which $W_P=-W_Q$. It is remarkable that when the condition $R_0'/S_0'=R'/S'$ is secured, the whole of the correcting term involving N and W vanishes. The adjustment $R_0'/S_0'=R'/S'$ has been very generally secured in practice with a view to

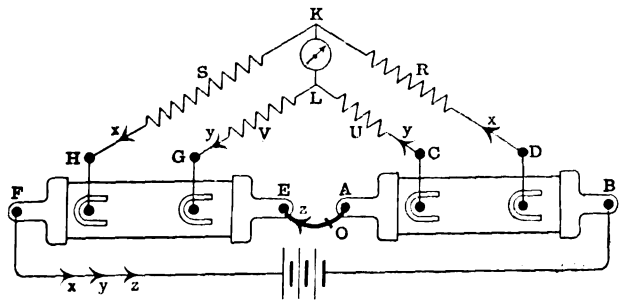

Fig. 25.

eliminate any correction for the resistance of the connector. But it appears that the undesigned advantage of eliminating the correction depending upon W has been gained at the same time.

The quantity [CD . BD] which appears in R' may be determined by sending a current from B to D, and measuring the fall of potential from C to D, and likewise for [GH . FH].

When the conditions are such that the resistances R, S, U, V can be made large, the resistances [CD . BD] and [GH . FH] can be eliminated by making a second adjustment, in which R and S have the values R_1 S_1. The resistances U and V are again adjusted so that the balance holds good whether the connector is in place or not, We then obtain

$$P/Q=R_1'/S_1'.$$

Then,
$$\frac{P}{Q}=\frac{R'}{S'}=\frac{R_1'}{S'}=\frac{R'-R_1'}{S'-S_1'}=\frac{R-R_1}{S-S_1}. \quad . \quad . \quad . \quad (7)$$

In this case P/Q is given simply by the ratio of the change in R to that in S.

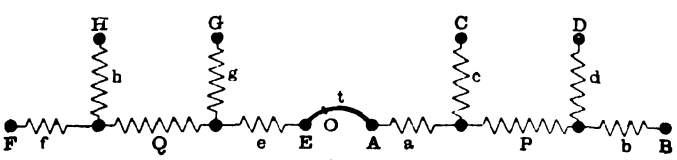

Fig. 26.

The second form of the condition for a balance is found by eliminating x, y, z from equations (1) to (3) without substituting X and Y for U' + P and V' + Q. We then obtain

$$PS'\{M+N+V'W/S'\}=QR'\{M+N+U'W/R'\}-N\{S'U'-V'R'\}.$$

Hence, since $M=U'+V'+W$,

$$\frac{P}{Q}=\frac{R'}{S'}-\frac{V'}{Q}\cdot\frac{N-QW/S'}{U'+V'+N+W(S'+V')/S'}\left(\frac{U'}{V'}-\frac{R'}{S'}\right). \quad . \quad (8)$$

This equation is useful when U'/V' can be accurately determined as well as R'/S'. This involves the determination of [DC . AC] and [HG . EG] by the fall of potential method. The equation used at the Reichsanstalt in comparing a resistance of 0·00001 ohm with one of 0·0001 ohm is derived from equation (8) by putting W = 0.

It may be useful to exhibit the values of R', S', U', V', N for the case in which each system can be replaced by a five-wire

Digitized by Google

model. In terms of the resistances indicated in Fig. 26, we have

$$R'=R+d, \quad S'=S+h, \quad U'=U+c, \quad V'=V+g,$$
$$N=a+e+t.$$

Since W_P and W_Q are zero for the five-wire models, the latter are inadequate to represent the general case.

Conclusion. The author desires to express his sincere thanks to Mr. F. E. Smith of the National Physical Laboratory for the great labour he has bestowed upon the criticising and discussion of the paper in its various stages; his help has been invaluable. Thanks are also due to Dr. Heaviside, F.R.S., and Dr. Bromwich, F.R.S., for mathematical assistance, and to Dr. E. B. Rosa of the Bureau of Standards, and Dr. St. Lindeck of the Reichsanstalt, for information as to the methods adopted in those institutions. Mr. G. M. B. Dobson, B.A., of Caius College kindly prepared the drawings for the illustrations.

PUBLIC ELECTRIC SUPPLY IN COUNTRY DISTRICTS.

We give below an account of the discussion that took place at the meeting of the Yorkshire Local Section of the Institution of Electrical Engineers on the 5th inst., when Mr. W. B. Woodhouse read his Paper on this subject.

Mr. W. Emmott referred to the discussion that took place in 1904 on this subject, when Mr. Woodhouse urged the necessity of his power company supplying Urban District Councils, as against a supply from the boroughs. About an equal division of opinion on the matter was shown. Things had altered considerably, and the speaker was now in favour of the lack of electric supply in the out-districts being met by the Yorkshire Power Co., as the municipal authorities now realised that they had quite work enough at home without extending their borders. Many districts were now supplied by the Yorkshire Power Co., to the satisfaction of both the consumers and the Company. It was impossible to estimate the value to an out-district, where rates were considerably lower than in the boroughs, of an electricity supply, as manufacturers were realising that it would pay to put down their works outside the boroughs, thus saving considerably in rates, paying less for land, and getting current for power and lighting on the most favourable terms. This practice was bound to increase, and he foresaw a great and successful future for the Company.

Mr. A. G. Lupton thought a supply of electric power was undoubtedly required in Yorkshire, particularly in the West Riding. The development had been much slower than he anticipated. A point not always recognised was that textile mills were formerly planned and built so as to have the heavy work near the engine and the lighter work at the far end of the shafting; with electric power the mill could be planned to suit the processes that had to be carried out, and not merely to assist the mill engine to carry its load. There were other important advantages in being able to run part of the works at night time, &c. He put efficiency first and economy second, and if the electric drive gave both these to advantage there was the further consideration that the smoke which disgraced the whole community should be got rid of. The waste of national resources could be limited by such general engineering schemes as those of big power companies. He believed they were on the verge of great improvements in social conditions arising from conservation of national forces and the benefits that would accompany it.

Mr. J. W. Hame (York), as a representative of a municipal electric supply undertaking, thought municipalities were very much indebted to the pioneer work which the large supply companies had done. Before the large companies on Tyneside and elsewhere commenced to develop their undertakings, very little was done by municipalities to supply current for power purposes. This had an important bearing with municipalities in their commercial development. One of the most interesting points in the Paper to a municipal engineer was the development of cottage lighting. The only commercial way at present to supply electricity for cottage lighting was by means of overhead wires. With reference to the Barnsley installation, he asked whether the overhead wires were used solely for public lighting or partly for public lighting and partly for domestic lighting.

Mr. S. D. Schofield agreed that it was undoubtedly impossible to supply country districts from a small station with underground mains, and that if a supply of electricity was to be given in country districts, it must be by taking a bulk supply from a power company or large power station, in conjunction with a small sub-station or transformers, with overhead lines and with a minimum maintenance cost.

Mr. E. A. Barker (Barnsley) gave a few figures with reference to the street lighting on the outskirts of Barnsley. At present two approaches to the borough were served with street lighting from overhead mains. The longer of the two was 1,100 yds. and the cost worked out at £93, including three-section steel poles, wires, insulators, lamp brackets, globes and service to overhead supply; about 1s. 8d. per yard. The author had stated that the cost of 36 street lamps was £100. At Barnsley the brackets and hoods cost 15s., so that the author's figure might be easily reduced to below £40. At the end of these overhead mains the District Council had street lighting by the latest type of incandescent gas, and a considerable amount of competition had taken place with regard to the relative costs. Several photometer tests had been made between the last Corporation electric street lamp and the first incandescent gas lamp in Dodworth (the District Council area), this distance being 90 yds. The balancing point of the light was on each test at a point 39 yds. from the gas lamp and 51 yds. from the electric, showing a penetrative power, in favour of the electric, of 25 per cent. The total annual cost of the electric street lamp was something like 3s. per post less than gas. With reference to Mr. Hame's query, no provision was made for domestic lighting, there being no houses in the district. In the distance of 1,100 yds. there were 11 lamps, each giving 100 c.p.

Mr. F. Thursfield said the smoke nuisance emanated largely from the domestic fire, and if small amounts of power could be provided at anything like the price at which large amounts of power were being supplied, there was a very large load indeed to be found for domestic heating by electricity. He did not think that the difference between the cost of producing electricity by the large power company and the small local authority was so great as the author made out. A small local authority with one or two oil engines could produce power in a small area very cheaply indeed. As far as fuel costs were concerned, it could work almost as cheaply as the larger concern. The chief difference was in capital outlay and in attendance. He thought Mr. Woodhouse had omitted the chief point in favour of the power company, viz., that the small urban authority was not justified in sinking much capital in a business which might in a few years' time become more or less antiquated. He was surprised by the author's statement that the annual revenue from a business supply rarely exceeded 15 per cent. of the capital expenditure. The cost of street lighting at £2 per lamp per annum was very low. At Chester they had a large number of these lamps, in fact, nearly every street gas lamp was converted, but he could not possibly get the cost of running below £3 per lamp. The author only counted on 2,000 hours per year; the usual street lighting hours amounted to over 3,000 per annum.

Mr. Holliday (Ardsley) assured members that some prejudice existed against overhead mains. If people could only see overhead mains taken along in such a neat manner as shown on the screen that evening it would go a long way towards removing the prejudice. The author had not made the most of one of his points with regard to extinguishing and lighting lamps. By switching the lights on and off simultaneously so many lamplighters were not required, and in a small district like Ardsley the saving in this direction would be at least £60 per annum.

Mr. I. Fawcett thought that a cottager who could afford to take 160 units per annum was a very good customer, and it would be cheaper to move than pay the bill. The difficulty of supplying farms was that they were generally off the line of the main road, and possibly off the line of the mains, and it did not look as if it would pay.

Mr. H. M. Sillar said that some small local authorities were debarred from starting an electric supply because they were afraid of the cost of a Provisional Order (£150 without opposition). He asked whether the author could advise very small authorities to start a supply without an Order; also whether it would be possible for several Local Authorities to obtain a joint Provisional Order and after that to work their districts separately.

Mr. H. Dickinson (Leeds) asked the author to give his experience in approaching the various Local Authorities or Urban District Councils, and whether he found much opposition to overhead wires. The author had made out a very good case, but he might have emphasised the general position of the bulk supply much more strongly than he had done; for instance, the great advantage of combination. Some time ago he (the speaker) went into the question of tramway supply in conjunction with lighting stations, and in comparing the results in other towns and taking the maximum load for lighting and the maximum load for traction, he found that in many cases the maximum traction load came in the summer and the maximum lighting load in the winter. There was an enormous saving in capital expenditure on plant. In the case of one combined station the saving in capital at £30 per kilowatt, including land, plant and buildings, worked out at £78,000.

Mr. W. Hartnell said that electricity, like everything else, must be produced at its lowest cost. He believed when the Post Office had this question of wires before the House of Commons the cost of installing the cables underground was mentioned as being six or seven times more expensive than to place them overhead, and the Post Office declined to put them down.

Mr. H. H. Wright said nothing had been mentioned of any competitive sources of cheap power. As wind was perhaps the cheapest form of power it might have some bearing on the subject of cheap production of power.

Mr. T. Harding Churton referred to the importance of using large units and overhead mains. Like every Englishman he had a lingering affection for the fireside, and thought it would be a long time before they abandoned the coal fire. As far as cooking was concerned, however, they did not feel the same sentiment.

Mr. W. B. Woodhouse, in reply, mentioned that 95 per cent. of the power used on the banks of the Tyne was supplied by the power company and the result was that the fogs and the mists that used to hover about had been enormously reduced and the amount of sunshine increased. The collection of small accounts was difficult, and the simplest way was to include it in the rent. Mr. Thursfield had thought he did not allow sufficient return on the capital. If, however, one took the accounts of most small undertakings it would be found that the gross revenue was

TRIALS BY THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION ON SPEED INDICATORS FOR TRAMCARS.

In 1908 the Tramways and Light Railways Association was re... by the Board of Trade to furnish them with its observations ... subject of speed indicators for tramcars. The matter was ... discussed at several meetings of the council, and in February, ... a circular letter was addressed to every member of the Associa... asking his views upon the subject. Fifty-eight replies were ... and discussed by the council, with the result that the Board ... were informed that no indicator on the market satisfied ... conditions, and that this class of instruments was not ... to fulfil a useful function on tramcars.

As a result, however, of further correspondence with the Board an ... appeared in the technical papers in June, 1909, offer... trials for official trials of any speed indicators of merit. ... replies were received, and a committee consisting of ... R. W. Cramp (Birmingham & Midland Tramways), H. ... (West Wakefield), W. E. Ireland (L.C.C.), C. W. Mallins (Liver... A. H. Pott (Metropolitan Electric Tramways), Sir Clifton ... (London United Tramways), J. R. Salter (Lancashire ... Tramways) and S. Sellon were appointed to carry out trials ... report on the various instruments submitted.

The conditions under which the tests were carried out and the pro... which was adopted by the undertakers carrying out the tests ... indicators, together with a description of the instruments ... and transmission gears and the detailed results of the tests, ... in the April issue of the "Journal" of the Tramways ... Railways Association. Ten instruments were finally ... and each competitor had also to design and supply his ... gear.

In the general remarks with which the committee conclude their ... it is pointed out that the majority of the makers submitting ... instruments were unacquainted with the difficulties met with ... working under tramway conditions. The instruments had ... been designed (1) for experimental work on locomotives, ... and stationary engines, (2) for stationary engines alone ... motor cars. Instruments of the first of these classes are, ... remarks point out, suitable for tramway work, though they ... special adjustments and are expensive. Speed indicators ... for use in the second class are generally quite unsuited for ... work. The instruments in the third class, which are de... motor cars are usually adaptable to trams, though some ... instruments submitted were handicapped by faulty trans... gear. When it became evident that the transmission gear ... the chief difficulty it was decided that all makers' instru... should be, as far as possible, tested on the same type of car—... bogie trucks—this being the most suitable type, as it is easier to find a position in which to fix the gearing. The cheapest and easiest transmission is from indicators actuated by dynamos. This is also the cheapest form of indicator where they have to be fixed at both ends of the car. In considering the best form of transmission gear, it must be borne in mind that almost all types will be damaged on bogie cars by a derailment, unless the gear is designed to come adrift when the truck radiates too much. When only an insulated wire runs between the truck and the platform, the damage is limited to the rupture of the wire. There is no doubt that all-mechanical transmission gears must be strongly made and encased throughout, so as to be protected against mud and water. Moving parts must, however, be accessible for lubrication. There is possibly not much improvement required in the design and workmanship of instruments by leading makers. The centrifugal patteras are usually cheaper, but have the disadvantage of not recording at very low speeds. The cases should always be as weather-proof as possible.

It is pointed out by the committee that there is a strong feeling among some engineers and tramway managers that it is most undesirable to place anything on the car which may tend to withdraw the motorman's attention from the road. It is suggested that the fitting of speed indicators might act in this way, especially with young motormen, and lead to accidents which would otherwise have been avoided.

From a careful consideration of the tests of speed indicators which were specially submitted for the Tramways and Light Railways Association tests, and of others previously tested, the committee have formed the following conclusions:—

1. That there are now speed indicators on the market which, so far as the instruments themselves are concerned, have worked satisfactorily during the tests, although it is not at present possible to state what their life is likely to be when fixed on tramcars.

2. That transmission gears could be made which might stand for some time the rough conditions met with underneath a tramcar; their first cost and maintenance, however, must be considerable.

3. That in view of the first cost and the cost of maintenance of instruments and transmission gear it would be a serious burden on tramway undertakings to have to equip service cars with indicators.

4. That as the proper maintenance of the existing equipment on a car already fully occupies the attention of the staff during the short time available between cars leaving and returning to the sheds, it is most undesirable to add anything more to a car which will require attention, especially if this is not a vital part of the equipment.

5. That the electrical form of speed indicator is the cheapest and easiest to fit, but from the tests it will be seen that indicators of this type appear unable to stand the rough conditions of tramway operation.

6. That if speed indicators are required at all, they should only be fitted on cars for instruction and test purposes.

7. That except for special test purposes, no speed recording chart is necessary, and a mileage recorder is not required.

8. That no indicator showing the maximum speed attained (by ringing a bell or moving a maximum pointer) is of much value, as the authorised speed varies at different parts of the same route; and whereas it may be safe to exceed a speed of, say, 16 miles per hour on one part of a route, it may be dangerous on another part of the same route to exceed even 4 miles per hour.

9. That since the most successful form of transmission is that in which a belt or chain is driven from one of the car axles, the wear of the wheel will necessitate a constant adjustment of the instrument, otherwise there would be a considerable inaccuracy in the reading of the indicator.

Electrification of Chicago Main Lines.—According to "Engineering News" a railway electrification committee has been appointed by the Chicago Association of Commerce to investigate the problem of converting the steam railway terminal lines to electric traction. The railways are represented on the committee by the presidents of the Chicago & Western Indiana Railway, the Chicago & Northwestern Railway, the Chicago, Burlington & Quincy Railway, and by the vice-president of the New York Central Railway. The city is represented by the Chief Smoke Inspector, the Health Commissioner, the chairman of the City Smoke Commission and the chairman of the council Committee on Local Transportation. The other members are Dr. W. F. M. Goss, of the University of Illinois, the president of the Northwestern Elevated Railway, and several business men. The committee will appoint a chief engineer and engineering staff and will maintain permanent headquarters.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in streng cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Prize 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. A COMPLETE TREATISE. *Ready in April.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *in Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hörner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (Gratis) the Index to Vol. LXVI. This includes the Index to the "Industrial Supplement."

Complaints of non-receipt should be promptly made to the Publisher.

READY APRIL 25th.—Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

SPEED INDICATORS ON TRAMCARS.

About two years ago some correspondence passed between the Board of Trade and the Tramways & Light Railways Association in regard to the employment of speed indicators on tramcars. The Board were of opinion that the evolution of an instrument for this purpose should be encouraged, and that it should be used at least for the purpose of training the drivers. Although the Association did not welcome the idea of using speed indicators to any great extent, they were quite willing to carry out tests on instruments supplied by the makers and to report generally on the results of such tests. Consequently, an advertisement was prepared asking makers to submit instruments and laying down terms on which the trials would be conducted. The Report has now been issued, and appears as the April number of the "Journal" of the Tramways and Light Railways Association.

It is, perhaps, a little unfortunate that the trial of the speed indicators was complicated by that of the transmis-

Digitized by Google

...ion gear, and that the makers of the instruments were ...sponsible for the latter also. The design of a really satis... ...ion gear for transmitting motion from the bogie wheels ...o the indicator is by no means easy. It requires both ...me and money. Not only must any vertical oscillatory ...ovement of the car frame be taken into account, but pro... ...ision must be made for the very large angular movements ...f the bogie in regard to the frame. This necessitates a ...ear with a great deal of freedom and many working parts, ...all of which are subject to wear and require maintenance. ...It is, in fact, the sort of thing that is repellent to the de... ...igner anxious for simplicity, cheapness and certainty of a ...good result. We do not doubt that some makers felt that it ...was not worth while to spend time and money on a problem ...of this kind when there was no certainty of a return, but ...only a possibility that someone else would profit by their ...efforts.

Finally ten instruments and gears were received, and these ...were tested by running up to some thousands of miles; but, ...as might have been expected, the tests were quite as much ...tests of the transmission gear as of the instruments. On ...the whole, we think it would have been better if makers ...had, in the first instance, been asked to send in a design ...of the transmission gear they proposed to use. Since most ...instruments require the same type of drive, it would have ...been easy to select the best design, or to combine designs ...to give the best result. The number of designs used would ...then have been reduced to a minimum, most of the com... ...peting makers would have been put to the least possible ...trouble, and the different instruments would have com... ...peted on more equal terms. As it was, the Committee ...state that "some of the instruments which did not give ...very good results might have been quite satisfactory with ...more suitable transmission gear." It is also stated that ...while there is not much improvement required in the ...design and workmanship of instruments by leading ...makers. This remark applies to indicators of the class ...used on motor cars; not to those used for experimental ...work and on stationary engines as these are obviously un... ...suited for the arduous life experienced on a tramcar.

The Committee conclude that there are speed indicators ...on the market which have worked satisfactorily, but that ...it is impossible to state what their probable life would be ...on a tramcar. The position in regard to transmission gear ...is more clear. Such gears might be so made as to stand ...for some time, but the Committee are afraid that their first ...cost and maintenance would be considerable. This, it is ...said, coupled with the cost of the instrument, would be a ...serious burden on a tramway undertaking if service cars ...were to be so equipped; also, that the staff already have ...their hands fully occupied without adding further equip... ...ment requiring attention. The view is taken that if speed ...indicators are fitted at all this should only be done for ...experimental or test purposes.

There is no doubt that these conclusions can be pretty ...well supported. One of the weak points of nearly all ...instruments is that the indication depends upon the ...size of the tyre, and as this wears down, the indicator ...becomes inaccurate. By designing the gear to be correct ...for the mean diameter of the wheel the maximum error due to this cause, as stated in the Report, will not exceed 7 per cent. This is still rather a large error, but its elimination would necessitate periodical adjustments of some kind.

Some tramway engineers hold the view that a speed indicator on a car would withdraw the driver's attention from the road, on which it ought to be fixed, and that accidents would occur in consequence. We very much doubt if any such difficulty would be found to arise, because the indicator would not be the primary object in the mind of the driver; no such trouble, for example, arises in the driving of motor cars, in which quite as keen a look-out is necessary. As to whether speed indicators would prove useful from the point of view of safety, we think much must depend upon the character of the road. If the road is straightforward we do not see what would be gained, though drivers should be trained to know something of the limiting speed, for it is scarcely fair to prosecute the drivers of motor cars for exceeding the limit if drivers of tramcars can do so with impunity. On the other hand, where gradients are heavy, and special speed limits have been imposed by the Board of Trade for the sake of safety, we think speed indicators might prove a valuable safeguard. Only those who have driven and observed the speed by means of an indicator realise how very quickly the low speeds sometimes specified by the Board of Trade are reached; and yet safety, when the track is in a greasy condition, may depend upon the strict observance of these regulations.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Solectrics: A Theory explaining the Causes of Tempests, Seismic and Volcanic Disturbances, and How to Calculate their Time and Place. By ALFRED J. COOPER. (London: J. D. Potter.) Pp. ii. + 100 10s.

Lothar Meyer in his "Theoretical Chemistry" states that the proper method of investigating the correctness of any theory or hypothesis is, without reference to the facts, to deduce from it all logical conclusions, and then to compare these deductions with the actual facts; if the facts agree with the conclusions the theory attains a high degree of probability. The author of "Solectrics" by no means pursues this method. He supposes the sun to be the source of a universal energy, embracing all known forms of energy, and he calls this Solectric *force*; then, taking the phenomena which he wishes to explain, in turn, he endeavours to fit his theory round them. Judging by the fit, and also by the curious things it is made to do, "solectric force" would appear to be highly elastic, rather than plastic. The greater part of the book consists in calculations respecting the relative positions of the sun, moon and planets on the dates of past storms, earthquakes, &c., and on these occasions solectric force generally appears as a kind of static charge of electricity; but in the first 18 pages the general theory of solectric force is explained, and it there seems to be a continuous current of electricity. The solectric explanation of the rotation of the earth on its axis may be given as an example—it is very simple and weird. To begin with, solectric force does not behave as an ordinary decent rotor quantity, but it has, nevertheless, two components, called the vertical and horizontal respectively, but not drawn at right angles to each other. The vertical component is a continuous electric current "permanently acting on the side of the earth turned towards the sun," and also "circulating freely past it." This latter behaviour explains the obliquity of the ecliptic, the earth being analogous to a permanently deflected galvanometer needle.

Digitized by Google

The horizontal component is also an electric current and encircles the earth a number of times. The interaction of these two components produces rotation, because wires carrying currents flowing in the same direction attract each other, and vice-versa!

The author says that the solectric theory is founded on the dynamical laws of electricity, and he explains that Newton had not the advantage of knowing these laws, but the whole thing would be much more plausible if the first 18 pages were omitted, and solectric force assumed to obey only new laws of the author's discovery. On p. 13 are two remarkable sketches, evidently a product of impressionistic art, showing "solectric power forcing a passage through the insulating atmosphere."

We are exceeding our space, but we hope the Editor will find room for one quotation, illustrating the author's graphic description: "Flaming blazes issued downwards and were returned by the earth upwards. A negro was in mortal fright, seeing great electric sparks passing from him. Can it be contended," asks the author, "that a storm is merely air in movement, after such evidence?" F.F.

Encyclopédie Électrotechnique. Part 35: Les Machines Electriques Alternatives à Collecteur. By L. Barbillion. (Paris: Librairie des Sciences et de l'Industrie.) Pp. 148. 2fr. 50c.

This booklet forms one of fifty-four parts of an encyclopædia of electrotechnics, 10 parts having now been published. The book under notice deals with alternating-current machines with commutators, one-half being devoted to rotary converters and the other to alternating-current commutator motors.

The treatment of the whole subject is of a mathematical nature, but a good knowledge of algebra and elementary calculus will cover all the mathematics used. For so cheap a book the arrangement and printing are very good, and the number of typographical errors is quite small.

The theory of rotary converters, both single phase and polyphase, is dealt with in a very clear manner. The compounding of rotaries is, however, only briefly mentioned; we think that this subject should have been treated more fully.

The greater part of the section on alternating-current commutator motors is given up to the theory of the repulsion motor. The proof that the transformer E.M.F. between the brushes is zero when the brushes are in the neutral position is, to our mind, rather laboured. The elementary mathematical theory of the single-phase commutator motor is given very fully, and compensated repulsion motors are briefly discussed. The treatment being of a theoretical nature, but little mention is made of the methods of preventing sparking at the brushes and other details of a more practical nature.

The book is so very inexpensive that it would be a good investment for the student who is of a mathematical turn of mind. To the student who is not mathematical the book will be of little use, for there is almost a complete absence of purely descriptive matter. A. E. C.

The Encyclopædia of Municipal and Sanitary Engineering. Edited by W. H. Maxwell and J. T. Brown. (London: Constable & Co.) Pp. xiv.+561. 42s. nett.

This volume is intended to provide a handy guide in all matters connected with municipal and sanitary engineering and administration. The constant addition to the duties and responsibilities of local authorities has doubtless rendered some such publication desirable, since it is obviously impossible for engineers and officials to keep themselves fully informed on all the subjects with which local authorities are now concerned. Many well-known experts have assisted in the compilation of the present work, which is of necessity very comprehensive. If, however, we are entitled to judge by those sections which deal, or ought to deal, with electrical matters, we must say that this encyclopædia leaves much to be desired as regards an impartial (or perhaps we might say modern) presentation of subjects of vital importance in municipal work. For instance, in the article on "Gas and Electric Light Testing" a table setting forth the comparative cost of illumination by various methods is given. Electrical energy is taken at 4d. per unit, and a 450 c.p. (250 watt) arc lamp, a 16 c.p. carbon glow lamp, and a 65 c.p. Nernst lamp represent electricity. It is not surprising, therefore, that the cost of 1000 c.p.-hours for these lamps, namely 2·2d., 12·5d. and 6·2d. respectively, compares unfavourably with that of the Welsbach mantle at 2·1d. (gas at 3s. per 1,000 cubic ft.), the intensified mantle (1·2d.) and the Kitson light (0·8d.) The Table is stated to be taken from the book on "Public Lighting" by the author of the article in question, Mr. W. J. Dibdin (formerly Superintending Gas Engineer to the London County Council), but attention should certainly have been drawn to the fact that these figures were in no way representative of modern practice. Again, in the article describing systems of heating, no mention is made of electrical apparatus; but under "Smoke Prevention" it is stated that electric heating can be dismissed as too costly. The solution of smokeless domestic heating is, by the way, looked for in the production of cheap gas at the coal fields, and its supply to our cities through high-pressure mains.

Turning now to the article under the heading "Electricity," we note that the subject is treated from the practical aspect, electricity being considered merely as "something which, consumed in sufficient quantities, serves to provide light and heat, and to propel tramcars and railway trains, and to drive machinery in workshops and factories." An unfortunate error occurs in the second column of the article, a quantity of electricity in kilowatt-hours being stated to be 1,000 times the product of the pressure in volts, the current in amperes and the time in hours. The error is the less pardonable since the writer proceeds: "In other words: kilowatt-hours = 1,000 × volts × amperes × hours." In dealing with power in a later paragraph the same mistake is repeatedly made, power being three times stated to be—

$$\text{kilowatts} = 1{,}000 \times \text{volts} \times \text{amperes}.$$

The brief description given of a flame arc lamp will scarcely be grasped by a non-electrical reader, since the hood of the lamp in the illustration is lettered to correspond with the reference to the carbons in the description. Both carbons are also said to be fed downwards, although the diagram illustrates one carbon vertically over the other.

Reference has already been made to the article on "Gas and Electric Light Testing." It may also be noted—to quote from the article—that "the tolerance shown by public authorities to the electrical industry by neglect to establish a severe system of tests and punishments for default in supply, as in the case of gas, has gone not a little way to encourage the growth of the newcomer in the field of luminous energy." A biased attitude is obvious throughout this article, and is to be deplored in an encyclopædia for reference by public officials.

As it is only possible here to refer to a few of the articles we may just mention that under "Thermometers" no mention is made of any for taking readings at high temperatures. Municipal tramways are briefly dismissed in some 4½ pages. In this section a Table, showing the summarised results of electric tramway operation in this country, would have been more useful if it had been brought more up-to-date than the financial year 1907-8.

A rather remarkable omission is that neither under the heading "Turbines," nor under "Steam Engines," in fact anywhere in the book, is mention made of steam turbines.

A NEW METHOD FOR THE ABSOLUTE MEASUREMENT OF ELECTRIC QUANTITY.*

BY BURTON McCOLLUM.

Summary.—The author describes a type of dynamometer of great sensibility which allows electric quantity to be measured with great accuracy. The proportional dimensions of the coils and the degree of accuracy obtainable are discussed.

In the absolute measurement of current two classes of method are available which are capable of considerable accuracy, viz. electrodynamometer methods and current balances. By the latter form of apparatus measurements of current have been made in which a higher degree of accuracy has been attained than with the first-named type. There are, however, numerous possible sources of error

* Abstract of an article in the "Bulletin of the Bureau of Standards.

Digitized by Google

in the use of the current balance, and, although most of these can be made small individually, they may, on account of their number, introduce uncertainty in the result.

In electrodynamometers of the ordinary types the dimensions of the windings must be known with extreme accuracy, thus requiring that the coils not only be wound with great regularity and measured with great care, but permanency of both size and form must be assured. In the Gray electrodynamometer a great difficulty still is met with in measuring the torque, due to the erratic behaviour of all materials available for the torsion wire. They cannot be depended upon to remain constant with time, they vary considerably even with slight changes in temperature, and they all have a greater or less tendency to take a permanent set when twisted. Again, both electrodynamometers and current balances have a rather troublesome temperature coefficient; and although artificial cooling may alleviate this condition somewhat, a certain amount of local heating is inevitable, and the consequent change in the dimensions may give rise to considerable variation in the constants of the instruments between the time of measuring the dimensions of the coils and the time of making a measurement of current.

There is here described a type of electrodynamometer which, when used to measure the electrochemical equivalent of silver, appears to be free from the objections referred to above, without introducing other difficulties of a serious nature. The instrument consists essentially of a relatively large fixed coil, C_1, Fig. 1, with its axis in a horizontal position, at the centre of which is suspended the movable coil C_2, with its axis parallel to the axis of the fixed coil when at rest. Attached to the movable coil is a cylinder, K, of some homogeneous material placed with its axis vertical and coincident with the axis of suspension. This cylinder should be of very regular dimensions, and should have a moment of inertia as large as, or larger than, that of the movable coil. If these two coils be connected in series in proper relation, and a current sent through them, there will exist a couple tending to hold the movable coil with its axis parallel to that of the fixed coil, and if the movable coil be

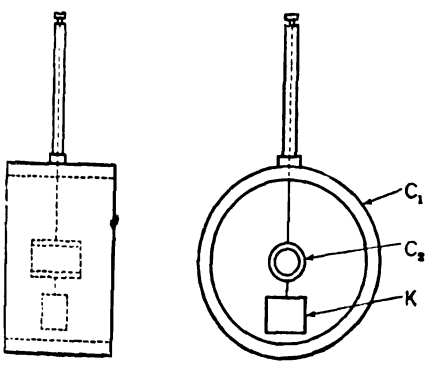

Fig. 1.

given an angular displacement and release, it will oscillate as a torsion pendulum. If now, the form of the field due to the fixed coils be such that the restoring couple is directly proportional to the angular displacement, a condition that can readily be realised, the period of the oscillation will be independent of the amplitude, and we shall have, in effect, a torsion pendulum subject to the laws of a simple harmonic oscillation.

The time of vibration of the moving system is, therefore, given by the equation $T = \frac{2\pi}{\sqrt{R\frac{K}{a^2}-\frac{a^2}{4K^2}}}$, where R is the restoring couple per unit angular displacement, a is the counter torque due to the damping forces at unit angular velocity, and K is the moment of inertia of the moving system. Since, as assumed above, the coils are so proportioned that the torque due to the current i is proportional to the deflection θ, we will have $R = Ci^2 + b$, where C is a constant of the coils, b the constant of torsion of the suspending wire, and R the total restoring couple. We have, therefore,

$$T_1 = \frac{2\pi}{\sqrt{\frac{Ci^2+b}{K}-\frac{a^2}{4K^2}}} \quad \text{and} \quad T_2 = \frac{2\pi}{\sqrt{\frac{b}{K}-\frac{a^2}{4K^2}}},$$

where T_2 is the time of vibration obtained when current is switched off. Solving for i we get

$$i = \frac{2\pi}{T_1}\sqrt{\frac{K}{C}\left(1-\frac{T_1^2}{T_2^2}\right)}.$$

This equation is exact, and shows that damping introduces no error in the calculated value of the current. If the apparatus be properly designed, the ratio $T_1^2 : T_2^2$ can be made small (not exceeding 1 per cent.), so that a very large error in determining this ratio would introduce but a very small error in the value of i. The ultimate accuracy with which i can be measured depends, therefore, on the accuracy with which the three quantities T_1, K and C can be measured. These quantities can be determined with a high degree of precision by methods indicated below. This apparatus and the above equation may be used for the absolute measurement of current, if such is desired.

The time of vibration, T_1, may be written t/n, where t is the total elapsed time and n is the number of vibrations occurring during that time. We have then

$$it = Q = 2\pi n\sqrt{\frac{K}{C}\left(1-\frac{T_1^2}{T_2^2}\right)},$$

where Q is the total quantity of electricity that has passed through the instrument while the movable system is making n vibrations. Thus the instrument may be used for the direct measurement of electric quantity. By using this equation as the working formula, a very high degree of accuracy should be possible. An inspection of the equation will show that it is not necessary that the current be maintained rigorously constant. Indeed, the current might fluctuate continuously within a range of $\frac{1}{2}$ per cent., or it might remain continuously too small or too large by as much as one part in 1,000, and the resulting error in Q would not exceed 1 part in 100,000. The ultimate accuracy with which Q can be determined depends, therefore, on the accuracy with which n, K and C can be determined. Suitable methods for determining these factors are described below.

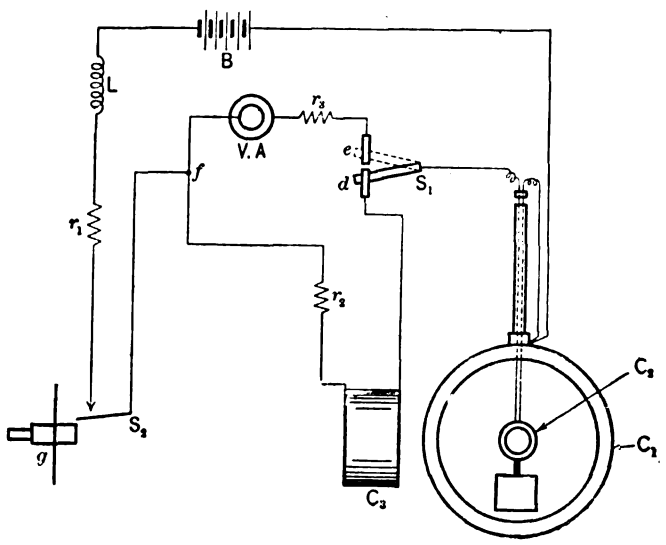

Fig. 2.

Determination of n.—A typical arrangement of the apparatus is shown in Fig. 2. B is a battery supplying current through the regulating resistance r_1, to the coils C_1 and C_2 of the electrodynamometer connected in series. S_1 is a single-pole double-throw switch which at starting is thrown over to the terminal d, so that the current is made to flow through the control coil C_3 which holds the movable coil C_2 at any suitable initial deflection (which need not be measured). The resistance of the circuit df should be previously adjusted nearly equal to that of the circuit ef, which contains the voltameter VA, and the terminals d and e adjusted so that the switch S_1, when thrown over, makes contact with e an instant before breaking the current at d. When ready to start the experiment, the switch S_1 is quickly thrown from d to e which starts the current in the voltameter circuit ef, and at the same time breaks the circuit of the control coil C_3, thus releasing the movable coil C_2, and the vibrations begin. The instrument should then be permitted to swing freely for a sufficient length of time to permit the deposition of enough silver for accurate weighing, during which time the number of complete vibrations of the movable coil is counted. When it is desired to stop the experiment, a reading should be taken of the last maximum deflection θ_0 at the end of n_0 complete vibrations, and about a quarter period later the current should be switched off, and at the same instant the position of the movable coil in its cycle and also its direction of motion should be noted. From these data, the value of n, the total number of vibrations, can be readily determined. In order to determine the position of the coil at the instant of opening the circuit, a telescope and scale, g, and reflecting mirror should be provided as in ordinary galvanometer work. Since the scale is in motion its position must be determined by obtaining

Digitized by Google

a momentary view of it at the instant of opening the circuit. Numerous ways suggest themselves for accomplishing this, one of the simplest, perhaps, being as follows: A portion of the scale, preferably the central portion, should be somewhat heavily shaded so that its reflection in the mirror will be very faint, if not invisible. A specially designed switch, S_2, which is used to open the circuit, should be placed near the shaded portion so that the flash caused by opening the switch will illuminate the scale for a brief instant. If, then, the switch be opened when the shaded portion of the scale is being reflected into the telescope, the scale will appear stationary, and its deflection, θ, can be easily read. The brightness of the flash can be made ample by including a self-inductance, L, in series with the circuit if necessary.

The author next shows that $n = n_0 + \frac{1}{2\pi}\cos^{-1}\theta/\theta_0$, where θ is the final deflection, and that the greatest accuracy is attainable if the final reading is taken when θ is small. Assuming that the experiment has continued for at least half an hour, that the period of vibration is 15 seconds, that the final reading is taken when θ is less than $\frac{1}{10}\theta_0$, that the scale is 2 metres from the mirror and that θ_0 equals 1/25 radian, the author calculates that an error as great as 1 mm. in the final reading of the scale would introduce an error of less than 1 part in 120,000 in the value of n, and that any small error in reading θ_0 is reduced 7,536 times in the value of n. With reasonable care, therefore, the precision of the measurement of Q would depend only on the determination of K and C.

Determination of K.—In order that K may be determined accurately, the movable coil should have attached to it a cylinder of some homogeneous material suspended with its axis vertical and coincident with the line of suspension. It should be made of some material that is known to be of uniform density and should preferably be of high electrical resistance so as to avoid excessive damping. Brass and other metal castings are objectionable because of the possibility of blow-holes and other defects which cannot be detected. Glass would seem to be a suitable material. A carefully made cylinder of glass would be expensive, but it would have the great advantage that any inequalities could readily be detected by simple optical tests. It would also be free from damping effects due to induced currents. The moment of inertia of such a cylinder carefully ground to size could be determined with great precision by calculation from its mass and dimensions. The most obvious method of determining the total moment of inertia of the system would be to take readings of the time of vibration, first without the glass cylinder attached and again with this cylinder in place. There are two objections to this method, however. The chief objection is that the torsion wire is subjected to considerably greater tension in the second part of the experiment than in the first, and this would undoubtedly affect appreciably the torsion of the wire. This disturbance could be greatly reduced by using a multifilar suspension, but even then it would probably be troublesome. Further, it is practically impossible to find a torsion wire that can be depended on with certainty to remain constant even under constant stress. These errors can be almost entirely eliminated, however, by making a constant current flow through the coils while taking the period, and there would be no difficulty in making the electromagnetic couple ae least 99 per cent. of the total couple.

Determination of C.—Taking the formula given by Gray* for the mutual inductance between two coils, the author finally shows, with the ratio of length to diameter of the fixed coil $\frac{\sqrt{3}}{2}$ and of the moving coil 2.062, the radius of the fixed coil should be 5·4 times that of the movable coil and that C is given by $\frac{2}{10}M_0$, where M_0 is the maximum mutual inductance, the coils being placed in that position.

The final working formula is, therefore,

$$Q = 2\pi n\sqrt{\frac{10K}{9M_0}\left(1-\frac{T_1^2}{T_2^2}\right)}.$$

The possible sources of error are discussed in the article at some length. It may be noted that the foregoing method for the absolute measurement of electric quantity has not yet been subjected to experimental test, so that the limits of the ultimate accuracy attainable by it cannot be stated with great precision. As compared with the Gray type of electrodynamometer and some types of the current balance, this instrument possesses, in common with the Rayleigh type of current balance, the advantage that errors in the dimensions of the coils are reduced manifold. The Rayleigh balance, however, possesses this advantage in greater degree. The method here described also possesses an advantage over the Gray electrodynamometer in that the torsion of the suspending wires is eliminated. Further, the fact that the indications of the instrument are in a large degree independent of the temperature of the movable coil and of moderate variations in the strength of the working current, contributes greatly to the convenience and to some extent to the accuracy of the method. As to the sensibility of the instrument, it seems that owing to the very great apparent travel of the scale, which, as a rule, would be from 100 to 200 metres, the sensibility of the instrument may safely be said far to exceed the limits of accuracy aimed at in absolute measurements at the present time. The constant of the instrument can be redetermined at any time without disturbing the coils by simply measuring their maximum mutual inductance, and this affords a convenient and accurate check on the stability of the instrument, which would in turn increase considerably the confidence that could be placed in individual measurements. The further fact that the quantity of electricity may be obtained directly without any knowledge of the value of the current being necessary, might often be of advantage where the electrochemical equivalent of silver or other metals is being determined, or, in other cases, where the time integral of current is required.

BETTINGTON DUST FUEL BOILER.

At a recent meeting of the Yorkshire Local Section of the Institution of Electrical Engineers a new type of boiler was described. The following particulars are based on the remarks made:—

This boiler is of the vertical water-tube type consisting of mild steel top and bottom headers connected by straight steel tubes, the top header being fitted with doors for drawing tubes. A brick lining surrounds the innermost circle of tubes to form the furnace, an important feature being that no binding material is employed for these special fire-bricks. The tuyere or fuel pipe is surrounded by a water jacket into which the feed water is fed, thus forming at the same time a mud drum.

The coal is fed or shovelled into a hopper placed at the side of the pulveriser and from there by a revolving worm to a chute which leads directly into the pulveriser casing. The pulveriser acts also as a blower, and after the coal has been disintegrated it is delivered up into the dust chamber, the finer particles passing direct to the fuel nozzle, the coarse particles returning by gravity to the pulveriser for re-grinding. The gases, on leaving the boiler, pass through an air heater, thereby pre-heating the air prior to its being drawn into the pulverising fan. By thus pre-heating the air, coals containing up to 15 per cent. moisture, or even more, can be easily disintegrated and burned. Slides are provided in the pulverising fan intake for regulating the amount of air, and the coal feed is controlled by means of a friction wheel driven from a shaft or by an adjustable slide in the hopper. The amount of air and coal can be instantly regulated and varied between very wide limits, thus immediately increasing or decreasing the rate of firing to suit any variations in the demand for steam. The fires may be extinguished and re-lighted in a few seconds. The greatest amount of evaporation takes place in the inner row of tubes. The circulation being rapid and the tubes vertical the scale deposit is much less than what would occur in inclined tubes, where the tendency would be for the scale to settle on the lower side and, under sluggish circulation, to burn on in patches, resulting in blisters or boils. In this case it is ejected from the tubes by the rapidly circulating water, returns to the bottom header where there is less ebullition, settles, and is in due course blown out.

It is well known that practically perfect combustion of a finely pulverised fuel can be secured by the introduction of such fuel, with a proper admixture of air, into a heated furnace. Such a mixture of air and fuel dust can be considered as a coarse gas, containing all the elements necessary for complete combustion. A true gas so constituted is explosive; but in the less intimate mixture of a solid and a gas, the rate of transmission of the point of explosion is comparatively low, and under the ordinary conditions of storage, mixture and transmission to furnaces no explosions are possible. In fact, this difficulty of ignition necessitates the surrounding of the discharge of mixed fuel and air with a furnace of incandescent fire-brick.

Hitherto, although the benefits to be derived from pulverised fuel have been taken advantage of at places for burning cement in special kilns, no commercial success has been established in its use for firing boilers. The broad principle now adopted, and which, in combination with special details, has solved the difficulties met in all previous arrangements of the combustion chamber, consists in the use of a vertical gas jet inlet so constructed that a mushroom-shaped

Digitized by Google

flame is produced within a closed ring of vertical water tubes, which are part of the steam-producing plant.

The heating up and continuous ignition of the incoming stream of dust and air is effected primarily by the enveloping sheath of products of combustion, now a true gas, or rather a mixture of gases (principally CO_2, H_2O, and N) and at a temperature of about 3,000° F. Obviously this "self-igniter" can never change its predetermined position, no matter how great a velocity is given to the incoming stream of combustible mixture. Ignition is now independent of the incandescent brickwork, which hitherto was in turn dependent upon its proximity to the point of explosion for incandescence. As an experimentally demonstrated fact, the point of explosion does not rise more than about 10 per cent. under the highest feed velocities it is practicable to employ. The tendency is for the enveloping gases to increase slightly in temperature as the velocity is increased. At the same time these returning gases always ensure incandescent brickwork around the tuyere. This has the advantage of storing heat, which is sufficient, after a temporary stop, to re-start the fire by merely turning on the fuel supply. Obviously with gravity and momentum acting in the same direction, *i.e.*, vertical stream lines, no separation can take place in a continuous stream of mixture, no matter how great a difference there may be between the specific weights of its constituents.

From the above it follows that the amount of air used can be reduced to the minimum required for the chemical reactions involved. The mixture, which it is most important should be as thorough as possible, is made before the "coarse gas" is projected into the furnace. As the solid portion forms theoretically only 1/11½th part by weight and an infinitely smaller part by volume of the mixture, it is safe to assume that owing to friction it enters the furnace through the tuyere at the same velocity as its accompanying air, which at this point is relatively high. But, owing to friction and expansion, the air very soon loses part of its initial velocity, but not to the same degree as the coarser particles of coal dust. Although these take fire immediately on entering the furnace, they take an appreciable time to become completely oxidised.

The ash of the fuel in its passage through the zone of highest temperature is converted into a liquid spray. A portion of this liquid spray strikes the brick lining of the furnace and in time trickles down to the bottom edge, being kept in a molten state by the descending hot gases, till it finally reaches the lower or "dripping" edge of the furnace proper. Being unable to adhere to the water-cooled surface it drips and falls clear to the ash pit, which, being relatively cool, chills the ash sufficiently to prevent the succeeding drop from adhering to it. The result is that the furnace automatically keeps itself perfectly clear of slag at all rates of combustion, and deposits the same in a manageable form, *i.e.*, small globules ¼ in. to ½ in. diameter, which are easily discharged to an ash conveyor or raked out periodically—an operation requiring but a few minutes, and not likely to be done at most more than once in 24 hours. This liquid spray also serves a very useful purpose. It renders it possible in running the furnace to dispense with the use of fireclay; the refractory bricks are merely stacked in position, and on firing up for the first time the gases naturally take advantage of all crevices to find their way out to the stack. As even the best coal contains some slag, this, being in the form of a liquid spray, also attempts to escape, being sucked through with the gases. But as this slag reaches at a relatively high temperature it very soon chokes up and hermetically seals all crevices and even large holes, at the same time coating the lining into one solid piece, as well as glazing the inner surface as though with a smooth enamel. Experiment has shown that even large holes several inches in diameter automatically close up, as well as any space there may be between the top edge of the brick lining and its water top, thereby entirely preventing all possibility of short-circuit of the gases.

The combustible mixture enters the furnace along its central axis, and soon after, and undergoes its most intense reaction in what is termed the "point of explosion" for want of a better name, after which it continues its path until deflected either by a layer of gas or the water-cooled metal top and in doing so is partially cooled. This partially cooled gas in which combustion, except for the coarser particles, has virtually ceased, envelopes on its forward escape the "exploding" mixture, thus actually forming a protective lining of gas between the "exploding" mixture and the brickwork lining and the water tubes of the boiler, which, in turn, keeps down the temperature of the brickwork lining within practicable limits. But the "gas" lining, while preventing "blowing" (still one of the most destructive phenomena we have to contend with in any form of combustion), does not prevent the utilisation of the most useful heat waves, popularly known as "radiant heat," which are able to pass directly through the "gas" lining and be absorbed by the brick lining and water tubes without involving their direct contact with its source of production. The boiler heating surface radiating from the central source of heat prevents unequal expansion and contraction of any of the parts, thus preventing unequal stresses being set up.

Among the many advantages of this system and construction of boiler may be mentioned the following:—Elimination of all standby losses, the possibilities of using the cheapest kinds of fine coal, the rapidity with which the output can be varied and steam raised, the perfect system of controlling the amount of air supplied for combustion, the use of hot air, the free and unrestricted circulation of the water, the ease with which all the tubes can be visually inspected throughout their entire length, the prevention of all air-leaks through the outer casing, the reduction in floor space, and the small amount of supervision required.

Messrs. Fraser & Chalmers, Ltd., 3, London Wall Buildings, E.C., are the manufacturers of the plants.

CORRESPONDENCE.

MULTIPLEX TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 17th Mr. B. S. Cohen describes a method of multiplex telephony, due to Major George Owen Squier, of the U.S. Army. Referring to this, I beg to remark that this method is neither new nor is it the invention of Major Squier. In the "Elektrotechnische Zeitschrift," for 1907, p. 484, I proved, in the article "Uber Mehrfach-Fernsprechen," mathematically that with high-frequency alternating currents multiple telephony can be pursued, in so much that every current might be the vehicle of a special speech. The currents produced must have such a high frequency that they do not produce sounds in the telephone. I showed also that the best effect is procured if an adjustment is made for resonance. In this manner the alternating currents with the respective messages are separated at both ends of the line—at both the sending and receiving ends. In the above-named article I mentioned also that I was able to transmit simultaneously five messages. I executed these experiments in the electrical laboratory of the Hungarian Post Office. A summary of this article appeared in the "Electrical World," 1907, Vol. XLIX., p. 1228, under the title "Multiple Telephony."

In the meantime I pursued my investigations relating to "multiplex telephony" with high-frequency currents. In the "Elektrotechnische Zeitschrift" of 1908, p. 1119, I published an article entitled "Uber Wechselstromtelephonie," in which I showed the advantages of alternating-current telephony, and remarked that by the tuning of the alternating current to the circuit the speech can be transferred along the circuit without distortion. I showed also that the higher the frequency the higher is the intensity of the speech, and that in this way the much-discussed problem of the telephone relay can be solved in the easiest way, advantages which with loaded lines cannot always be obtained. A summary of this article appeared in the "Electrical World," 1908, Vol. LII., p. 1307, entitled "Alternating Currents for Telephony."

In the meantime I reported my experiments to the first Conference of the European Post and Telegraph Engineers, and I communicated to the Conference the fact that I was able to transmit messages on a line 15 km. long. This communication is to be found in the "Comptes Rendus de la première conférence technique des administrations des postes et des telegraphes à Budapest," 1908, p. 31. After these publications there appeared in the "Elektrotechnische Zeitschrift," of 1909, p. 160, an article signed by Mr. Weinberg (of Washington), in which Mr. Weinberg not only verified my experiments on alternating-current telephony, but also proposed this method for trans-Atlantic telephony, a problem not yet solved to-day. A summary of this article also appeared in the "Electrical World," 1909, Vol. LIII., p. 645, under the title "Alternating Current for Telephony."

Later I worked much on the improvement of methods of multiple telephony, and in the "Elektrotechnische Zeitschrift," of 1909, p. 902, in an article entitled "Zur Mehrfachtelephonie" I described a more complete form of multiple telephony, which can be obtained by the use of electrolytic valves. In this case every alternating current is the vehicle of two messages, so that with the aid of n currents $2n$ messages can be transmitted. In the above-mentioned article I pointed out the great advantages of using high-frequency alternating currents for multiplex telegraphy, and the schemes which I found best for this purpose also appeared. A summary of this article also appeared in the "Electrical World," 1909, Vol. LIV., p. 1058, under the title "Multiplex Telephony."

It appears that the system of multiple telephony claimed by Major Squier is only a simpler form of my method published in the "Elektro-

Digitized by Google

technische Zeitschrift " of 1907, p. 484, and described also in the American " Electrical World," Vol. XLIX., p. 1228, in which my scheme is also reproduced, from which also it can be seen that Major Squier's method is only a simpler form of mine, because he uses it only for two messages.

I not only worked it out many years ago in the laboratory of the Royal Hungarian Post Office earlier than Major Squier, but I developed it and improved it with the aid of electrolytic valves to a greater degree than has Major Squier. All these methods and experiments were published in many European and American journals. And if Major Squier has dedicated this system to public use, I beg to remark that this was already done by the above-mentioned publications.

I publish these facts only to prove my priority.—I am, &c.,

AUGUST MAIOR,
Electrical Engineer of the Hungarian Post Office.

Budapest, March 24, 1911.

THE REDUCED CURRENT METHOD FOR LOCALISING FRACTURES IN SUBMARINE CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with Mr. Black's test, described in THE ELECTRICIAN April 7th, there is a simple empirical formula by means of which the distance to the break may be found from each reading. Balance having been found as described in the article referred to, the result, R, is equal to the resistance to the break plus the polarisation error plus the contact resistance. Mr. Black assumes, for practical purposes, that the polarisation error is inversely proportional to the current, and it has been found in practice to be equal to $\frac{100}{c}$ ohms, where c is the unreduced current to line in milliamperes when the balance is obtained. The contact resistance may be taken as approximately equal to the CR per naut (r) of the core at the exposure.

Then $$x = R - \left(\frac{100}{c} + r\right).$$

Applying this to the example given in the article:

1st reading: R=7,109$^{\omega}$, c=6 milliamperes, r=10$^{\omega}$, x=7,083$^{\omega}$.

2nd reading: R=7,127$^{\omega}$, c=3 milliamperes, r=10$^{\omega}$, x=7,084$^{\omega}$.

Actual distance, 7,088$^{\omega}$.

This test, with the above simplified formula, has given excellent results in practice.—I am, &c.,

Electra House, London, E.C., April 15. G. WALD.

WIRELESS TELEGRAPH WORKING IN RELATION TO INTERFERENCES AND PERTURBATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read with much interest Mr. Taylor's Paper on "Wireless Telegraph Working," and shall feel greatly obliged if you will publish the following observations on the subject.

Mr. Taylor considers the case of a directive aerial of triangular shape, excited on its fundamental oscillation. Now, the triangular aerial is only a particular form of the directive aerial. The ideal form consists of two vertical antennæ oscillating in one-quarter wave-length and spaced half a wave-length apart; these being joined at their lower ends by a horizontal conductor which serves to excite them. If the two antennæ are brought nearer together, or are inclined, the range and the radiation diminish, at first slowly and then rapidly. The whole aerial does not vibrate on its fundamental oscillation, but on the *third harmonic*. There are, in fact, three current loops and four potential loops on the aerial. It is well known that the effect at a distance is due to the current. If, therefore, a directive aerial is excited on its fundamental oscillation, the most useful part of the aerial—that containing the current loop—will be found in the horizontal portion, and the radiation from the aerial is very small. The conditions are quite the same as obtain where it is desired to increase the wave-length of an ordinary aerial by introducing a self-inductance at its base. The range diminishes as the wave-length increases, for the current loop becomes more and more shut up in the coil, which is unable to radiate. If, on the contrary, the same aerial be excited on its third harmonic, in such a way that there are two current loops at the lower ends of the vertical or inclined portions, the radiation will attain its maximum value.

Mr. Taylor, who kindly refers to our studies on directive aerials, contents himself with repeating the experiments of which the results were published three years ago; but since that date we have continued our investigations and experiments, concerning which Mr. Taylor evidently knows nothing. For he arrives at the conclusion that directive aerials are advantageous for " communication over short distances," and he would not have made this statement had he tried exciting his directive aerial on the third harmonic as we have been doing for a long time now.

We have made a series of very important comparative tests between a directive aerial which, excited on the third harmonic, gave a wave-length of 300 metres, and an ordinary aerial, equivalent to the other and giving the same wave-length. The measurements were made with a Duddell thermo-galvanometer at a distance away of 10 wave-lengths, and gave a ratio of 5 : 1 for the energy radiated by the two different types of aerial respectively, for the same primary input. Dr. Kiebitz has, independently, as a result of a long series of experiments, arrived at the conclusion that the directive aerial has a range " at least equal " to that of the ordinary aerial.

It is hence evident, contrary to Mr. Taylor's assertions, that by the use of a directive aerial the same distance can " at least " be obtained as with the ordinary aerial. Mr. Taylor's other assertion, that the directive aerial is limited to use with short waves, is also inexact; for Mr. Taylor is concerned solely with a directive aerial in a fixed position. Instead of employing a triangular directive aerial supported by a single mast, he has only to use a directive aerial made up of one horizontal and two vertical parts, the latter being each supported by a mast. Mr. Taylor has then only to separate the masts the necessary amount for him to be able to reach any desired wave-length. And we may add that with a single mast supporting a triangular directive aerial of suitable dimensions, and suitably excited, Mr. Taylor could easily radiate a 600-metre wave and attain at least the distance attained by an ordinary station of 600 metres wave-length. Thus the directive aerial is at least on a par with the ordinary aerial, even from the point of view of the length of wave which it can radiate.

In summarising what Mr. Taylor has written on this subject it appears that these aerials possess—from his standpoint—only one advantage, that is to say, directivity, with all its consequences; and three faults, which are: (1) Limited range, (2) impossibility of using a large wave-length, (3) use confined to two stations communicating exclusively among themselves.

We have shown that the first two defects are non-existent. The third defect, which would exist were it necessary to turn the aerial in order to change the direction of communication, does not exist either, owing to the fact that our directive system, having an antenna composed of *several* directive aerials, fixed in position and joined to a radio-goniometer allows of communication being effected in any desired direction. And since each directive aerial composing the antenna has neither the defect of reduced range, nor that of short wave-length, our system is on an equality with other systems, with the additional advantage of dirigibility. We may further add that by employing, as we do at present, instead of two directive aerials at right angles to one another, an antenna composed of 4, 6, 8 .... &c., aerials making angles with one another of 45 deg., 30 deg., 22 deg. 30 min. .... &c., joined to a form of radio-goniometer with 4, 6, 8 .... &c., fixed windings, we are able to attain a great range with aerials of reduced dimensions because we compose the effects of *many* aerials into a single very considerable resultant radiation.—We are, &c.,

THE LAYING AND MAINTENANCE OF TRANSMISSION CABLES.

Mr. C. Vernier's Paper on this subject, of which an abstract appeared in our issue of March 10th, was discussed by the Glasgow Local Section on the 11th inst. The following is a brief account of the discussion.

Mr. MITCHELL (Mains Superintendent, Glasgow) was surprised at the use of cast-iron troughs. In Glasgow they had abandoned these some years ago, mainly on account of electrolytic action on lead-covered cables. A great objection to cast-iron formerly was that it was made too rough in the inside. With regard to the filling in compounds used, bitumen cost approximately 2½ times the price of pitch. They had, in consequence, used pitch with satisfactory results for the last eight years. Recently they had been trying a mixture of pitch and ground or powdered stone. They found it quite plastic. One of their tests was carried in the form of a U and then reverse to ∩ without cracking. The mixture while being quite suitable was also very much cheaper. With regard to the covering of three-phase high-tension feeder cable he exhibited a wood model of a porcelain sleeve they were using in joint box; the sleeve was immersed in oil or special compound. The cable was bared unequally at both ends where the joint was to be made, and the porcelain clover leaf section insulator slipped on in place. The joints were made with sweated thimbles and the porcelain drawn over it to cover the bare metal work. There were rings on the porcelain to centre with the joint box, the glands in which were of the same material, taped or bonded as required.

Mr. D. M. MCLEOD (Clyde Valley Electrical Power Co.) preferred in the distributing system a duct laid direct in the earth. He instanced a case recently on their system where they were using cement ducts and in consequence the duct became severely cracked, intensifying the danger to the cables. He wanted something that would yield like lead. As to an efficient lubricant for a draw-in system, soft soap had objections, due to chemical action of the soap on the lead or cable. Petroleum jelly was quite good though more expensive. In experience he found flaked graphite by far the best. He considered the ring system the best for continuity of supply. They had experienced electrolytic action of wood on lead referred to and were now using Morrow's steel bridges for supporting the cables. He was also of opinion that armoured cables were the most efficient and the cheapest for transmission purposes.

Mr. VERNIER, in reply to the various points raised, recommended the use of cement ducts rather than fibre conduit. He found pitch cracked very readily, allowing moisture to penetrate the cracks. So far as cracking was concerned, the addition of whinstone would only increase this trouble, and he could not see how the elasticity was increased in any way by the reverse, and at the same time making it more or less brittle. The sleeve shown by Mr. Mitchell was certainly interesting, and showed the absence of oil between the various phases, that is the oil-tight joint in the porcelain surrounding and separating the various phases would not stop the creeping so well as the insulator he had round each phase. With regard to concrete ducts, he would suggest that these were more for protection against mechanical damage than and not against subsidences. His experience on the question of supply was that petroleum jelly was the best lubricant to use. The discussion was then adjourned to the May meeting.

DEVELOPMENTS IN THE MANUFACTURE OF ELECTRIC METERS.*

BY W. LUBACH.

Few developments have been made in this department of late years, though the general principles remain much as before; but the steadily increased demand for meters has reacted in such a way as to cause a general improvement to take place. The German Government reports that "a single factory is at the moment turning out 1,000 meters daily, and on all sides factories are being extended and enlarged. Half the output in Germany is for the export trade. In Germany itself there are 10 times as many meters in use as was the case 20 years ago, and similar progress seems likely to take place in the next 10 years." Statistics seem to show that the life of a meter is 20 years.

The increased demand for meters is due indirectly to the metal lamp, which has exerted the greatest influence on the specifications that are now issued. A meter for 10 amperes at 220 volts is quite a common one nowadays, but the main demand is for those taking from 3 to 5 amperes. A few years ago a shunt current of 0·03 or 0·04 ampere was allowable; but it is now sometimes found that the meter consumes more than the lamps in the case of a very small installation. It is, therefore, necessary that the shunt circuit should not take more than 1·5 watts on 110 volts. The metal lamp also requires greater exactness at low loads, besides the certainty of an easy start. It was usual to be satisfied if a meter read correctly on one-tenth of full load and started with one-hundredth; much lower figures are now being demanded. The conditions, indeed, are fairly stiff for a piece of apparatus that must not exceed a certain price, and in small meters it is difficult to comply with the specification, owing to the fact that the space available for the coils cannot be utilised to the best advantage. Alternate-current meters are generally made on the Ferraris principle; this works with a sort of short-circuited armature, and all the difficulties which occur in direct-current meters in passing the current through the system are non-existent. They can, therefore, easily be made to start on $\frac{1}{200}$th of full load, by increasing the torque by a suitable design for the coils. This has, in fact, been doubled without any increased cost. The no-load consumption has been reduced by providing a nearly complete iron circuit for the shunt magnetic field. With polyphase meters, which work on the two or three wattmeter method, the starting difficulties have not been altogether overcome, owing to the weight of the rotating parts, which consist generally of two discs. Electromagnetic vibrations have, however, been tried, and these act in such a way that the friction of the pivots almost disappears. By this method there is no fear of any reading on no load, because it does not depend on any arrangement for increasing the torque at light loads. A similar plan for neutralising the effect of friction magnetically has been in use in America for some time.

The effects of any fluctuation in voltage on alternate-current meters has been largely avoided by properly proportioning the leakage fields to those which act magnetically on the rotating parts; the newer types are also independent of any changes in the frequency. With small alternating-current meters for less than 3 amperes, there is the difficulty that the ohmic drop in the main circuit, added to the inductive drop, makes the total loss considerable. Very little improvement seems likely in design; many designs exist, and an equally large number have been dropped. Some improvement in the construction of the component parts may be possible, though little change is to be noticed in the recording mechanism. A meter for 5 amperes and 220 volts, with a maximum torque of 4 gr. cm., has a turning moment of only 0·1 gr. cm. with a load of one 25-watt metal lamp, and the slightest unevenness in the recording mechanism will affect it. It is probable that attention might profitably be directed to some method by which falling weights serve to drive the train through an escapement.

The watt-hour meter, constructed on dynamometric principles according to Thomson's design, is very simple and very cheap; but, owing to the fact that there is so little that is really capable of improvement, it remains much where it was. Sparking produces changes on the commutator, and the friction produced by the wear on the brushes tends to increase with each day of use. A much higher torque than is necessary with alternating-current meters might do something. It already amounts to 6 or 8 gr. cm., and on an average the loss in the main circuit amounts to 10 watts. The no-load losses have been reduced on three-wire circuits by connecting the shunt between the middle and one of the outer wires; but this is not free from objection, seeing that the voltages on the two sides of the system are not necessarily equal. There has been a good deal of difficulty in keeping the no-load loss below 1·5 watts on 110 volts. The Thomson type of meter is hard to adapt to modern demands. The auxiliary coil, used to counteract friction at the start, cannot be much increased in size without fear that the meter may read on no-load, and the friction between brushes and commutator is an ever variable quantity. It is, therefore, not possible to adjust it to start as definitely as the alternating-current type. Starting and sparking troubles have still to be completely overcome, though much work has already been done. Some makers have replaceable commutators and brushes, others move their brushes by means of a lever, so that the point of contact depends on the load. The device due to E. O'Keenan may be mentioned, by which the brushes are continually vibrated, thus neutralising friction, and allowing, as alleged, of a very easy start.

Meters constructed on the dynamometric principle are very sensitive to an external field; this has been specially noted now that accuracy at low loads has been much insisted on. Small errors have finally been traced to the magnetic effect of the earth's field, and some makers therefore provide their meters with astatic armatures. Pendulum meters with short pendulums are nearly free from outside influences, but their complicated construction seems likely to prevent their general use in small installations. Meters of the magneto-motor type have been much used of late years. They take no current at no-load, are independent of external magnetic fields, can be made even in the smallest sizes from ½ ampere to 3 amperes, and develop on the smallest loads a torque which is generally more than 10 gr. cm. Their construction has been much simplified, and the

Digitized by Google

price reduced. The contact-resistance between the commutator and brushes is variable, and in the newer types of meter the brushes are arranged so as to be movable along the commutator, and this movement is effected by means of a coil in series or in parallel with the brushes, which causes movement as soon as the contact resistance changes. The segments of the commutator are also shaped in a special way, so that when the brushes are displaced, the zone of commutation is similarly displaced. It is thus possible to produce an increase of torque, which is effective in the face of all kinds of likely forms of friction. To ensure a certain start the armature coils are so adapted to the shape of the permanent magnet that all the conductors on the armature contribute towards producing the torque. In the older forms, a start was not altogether certain even with 1 per cent. of full load; now it will start with half that amount, and sometimes even with less. The armature is often put in parallel with a resistance carrying the main current, and the fall of pressure amounts to 1 volt; in those meters in which the armature carries the whole current, the drop is 0·3 or 0·5 volt. These latter meters are not affected by the change of contact-resistance between commutator and brush, but if a short-circuit takes place on the installation the brushes are often destroyed and the commutator injured. For this reason such meters are often provided with very carefully adjusted fuses, or with small maximum cut-outs, which short-circuit the meter in cases of overload. Short-circuits are apt to affect meters of this type, the armature consisting only of a copper disc, which rotates in a bath of mercury. Some of the mercury may be thrown out of the bath, and often the strength of the permanent magnet is affected. The torque diminishes in proportion to the current, so that in the smaller sizes it amounts to 0·5 or 1 gr. cm. at full-load, and the instrument is apt to be very sensitive to friction of various kinds. It has, therefore, not found a large field of usefulness in small installations, but in larger sizes it has been very useful, and the voltage-drop in the mercury bath is usually less than 0·01 volt at full load.

Electrolytic meters are very correct on the smallest loads. The cells with mercury anodes have been much improved by the use of a solution containing the iodides of mercury and potassium as the electrolyte, and the formation of crystals, which affected the reading of the older types, is thus avoided. These meters have not been in use for a sufficient time for us to be able to be quite certain with regard to some points—*e.g.*, as to whether the process is always exactly reversible—and also whether traces of atmospheric gases and other slight impurities are entirely without effect in producing small disturbances. One defect is that there is no registering apparatus, and it is felt in some quarters that this is not entirely satisfactory from the point of view of the consumer.

LEGAL INTELLIGENCE.

Cruse & Others v. Willans & Robinson.

Mr. E. Pollock, Official Referee, has given judgment in this action by Mr. H. Cruse (trading as the Cruse Controllable Superheater Co.) and Messrs. E. Grether & Co. against Messrs. Willans & Robinson for the recovery of £10,000 damages for alleged breach of contract in regard to the manufacture by defendants of superheaters for plaintiffs.

The hearing of the case was commenced in Manchester on Oct. 5, 1910 (see THE ELECTRICIAN, Oct. 7, 1910, page 1082) but subsequently it was transferred to London. The case took 55 days and much technical evidence was given by both sides. By way of defence it was pleaded that the defects (if any) in the superheaters manufactured for plaintiffs were caused by faulty design, for which they were not responsible, as the machines were made to plaintiffs' own designs. Defendants also counterclaimed for £1,900, being balance of price of superheaters delivered, the cost of dies, &c.

In the course of his reserved judgment, Mr. Pollock said that the evidence of both sides proved that the superheaters did not fail by reason of faulty design, but entirely through bad workmanship, and he found for plaintiffs £3,535 damages, with costs on the higher scale.

White v. Darlington Corporation.

At Darlington County Court last week Mr. Jas. White sued Darlington Corporation for the recovery of £2. 6s. 4d. and £2. 5s. 2d., alleged to be overcharges on plaintiff's account for supply of electricity owing to defective meters installed by the Corporation.

Mr. G. TAYLOR, for the Corporation, contended that plaintiff was precluded from bringing the action in regard to the first amount as it related to the quarter from December to March, 1906, and under the Public Authorities Protection Act the action must be brought within six months of the act of default complained of.

Mr. G. F. LUCAS, for plaintiff, said his client applied to the Board of Trade for one of their inspectors to inspect the meter under the provisions of the Electric Lighting Act, 1882, but the application was refused. Considerable correspondence had taken place between the town clerk and his client with a view to a settlement, it being clear that the meter, which was not certified, had not properly registered consumption. It was not until October, 1910, that the Corporation definitely refused to refer the matter to arbitration, and that was well within the six months of the action. He submitted that he should not be stopped because he did not formally commence an action within six months of the complaint.

His HONOUR said that on the grounds submitted by Mr. Taylor he would have to give judgment for defendants in the first case, with costs. With regard to the second case, he thought the Corporation should make some concession to plaintiff, who had clearly been charged for more electricity than he had consumed.

After consultation, it was agreed that the Corporation should refund 5s. 2d. of the £2. 5s. 2d. which Mr. White had paid, each side paying their own costs.

Workmen's Compensation.

In the Manchester County Court last week Judge Mellor, K.C., was asked to confirm an agreement under which Manchester Corporation would pay £50 as compensation and costs to Mrs. E. Wood (a widow) for the death of her son.

Mr. FARRINGTON, for applicant, explained that Wood was employed as a cleaner of machines, but was expressly instructed not to touch any switchboard until it was certified safe by a superior officer. On Dec. 11 last he was sent to a sub-station at the works of the Metropolitan Amalgamated Railway Carriage & Waggon Co., Openshaw, to clean a machine. An hour after entering the sub-station he was seen to be enveloped in flames, and had received a severe electric shock. He died a few days later. Counsel was, however, unable to bring evidence to prove that the accident arose "out of and in the course of the man's employment." The Corporation had, however, offered to pay £43 and £7 for legal costs.

The JUDGE: But if the man went into the place in the course of his employment and came out in flames, surely that raises a presumption that he met his death in the course of his employment.

Mr. DEHN (for the Corporation) contended that this was not so, because the sum was in the nature of a gratuity, not a lump-sum settlement for an admitted liability. As the case had aroused public interest he wished to explain that the man was only sent to clean a rotary converter which was "dead" at the time. Instead of being content with that, he must have gone into a telephone box, obtained keys, opened a cubicle fastened by two padlocks, and unscrewed the front of the switchboard before coming into contact with the machinery.

The Judge accepted this explanation and confirmed the agreement.

Charges for Parcels on Tramcars.

At the Hastings County Court recently the Hastings & District Tramways Co. sued a passenger for 2d. for the carriage of a parcel. Mr. Pearson appeared for the company, and defendant (in person) argued that the parcel (a roll of felt) was personal luggage, and that as such he was entitled to carry it on the car, under the regulations.

The JUDGE, however, while declining to give a hard and fast definition, held that personal luggage consisted of "wearing apparel and things a person takes about."

Judgment was given for plaintiffs with costs.

PARLIAMENTARY INTELLIGENCE.

Rotherham, Maltby & District Rail-less Electric Traction Bill.—The promoters have decided not to proceed further with this Bill.

The Freight Tunnels of Chicago.—In a Paper read by Mr. W. E. Worth before the Electric Club of Chicago, the author gave some interesting information with regard to these tunnels, which are considered to be unique. The work done in them consists principally in removals of earth from the excavations of new buildings, the delivery of coal, the removal of ashes, and parcel traffic. Five different kinds of electric locomotives are used. A train consists of a locomotive and ten cars, each 12·5 ft. long and 4 ft. wide over all. The motorman constitutes the entire train crew. Ordinarily one man can handle eight train movements a day, or the equivalent of 80 carloads. One carload is about equal to the load on a one-horse dray. The largest locomotives are equipped with two 25 H.P. motors. An overhead trolley is used, and direct current at 250 volts is employed. It is asserted that the public freight-receiving stations receive freight packages which would otherwise require the daily employment of 1,200 waggons in the Loop district. The bottoms of the tunnels are about 42 ft. to 45 ft. below the street, though where the lines pass under the river, which they do at 12 places, the depth is increased to 65 ft. Electrically-operated pumps are used to pump the sewage into the sewers, which are on a higher level than the tunnels, and electrically-operated points are being installed. The average speed of the trains is about 8 miles an hour.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aldershot.—Application has been made for sanction to a loan of £2,500 for additional plant at the electricity works.

At the last meeting of the Council the chairman of the Lighting Committee (Mr. Calvert) called attention to the action of the local gas company in giving what he termed preferential treatment by making an offer of reduction to people who did not use electric light. He heard that there was a reduction to users of gas stoves, and he applied for the reduction, and thought he should have the same benefit as other users, especially as his consumption of gas and electric light was about equal. He was informed that because he used electric light in the house the reduction could not be made. It seemed to be a boycott of the electric light users.

The Clerk is to report upon the matter.

Association of Mining Electrical Engineers.—It is announced that the successful candidates at the recent examination for 1st class certificates of competency of electricians in charge of colliery installations include the following: Mr. F. Smith, electrician, Pinxton Collieries; Mr. E. Bearsdmore, engineer, Tibshelf Collieries; Mr. F. Church, electrician, Tibshelf Collieries; Mr. F. Cusworth, electrician, Summit Colliery, Kirkby; and Mr. E. Wilbraham, electrician, Ripley Collieries.

Beckenham.—The following return as to the use of electricity for lighting has been prepared for the Council:—

Ward.	No. of houses.	Free wiring.	Private wiring.	Per cent.
Copers Cope	563	128	94	39·43
Eden Park	735	115	93	28·30
Langley Park	400	85	126	52·75
Shortlands	370	73	148	59·73
Manor House	2,057	285	156	21·44
Kent House	1,472	171	56	15·42
Lawrie Park	1,388	99	43	10·23
	6,985	956	716	23·94

The L.G. Board have sanctioned a loan of £5,000 for "free" wiring, &c., on the understanding that the cost of lamps is not charged to loan account. The term of the loan is 10 years, as before.

Belfast.—The accounts of the tramways department for the year ended March 31 have been issued and show total receipts of £218,301, an increase of £14,426 over 1909-10.

The working expenses amounted to £112,959. 9s. 7d., an increase of £5,624. 8s.; and the working profit was £105,341. 8s. 11d., an increase of £8,801. 13s. 8d. Capital charges, including interest on loans, income tax, &c., amount to £51,290. 12s. 4d. The net profit amounted to £54,050. 16s. 7d., an increase of £7,754. 18s. 4d. The net balance is to be appropriated as follows:—Sinking fund, £24,025; depreciation fund, £13,000; reserve fund, £16,730. 1s. 1d.; general purposes fund, £295. 10s. 11d.

The estimated receipts for year ending March 31, 1912, are £235,000; working expenses, £125,000; working profit, £110,000; net revenue charges, £45,;000 net revenue, £65,000.

Customs Duties.—Supplements to the Australian Customs Tariff Guide state that the following duties upon imports will be leviable in future:—

Electrical appliances and materials and fittings: Adaptors, arc lamp automatic couplings, ceiling roses, wall rosettes with hooks for taking wires, electric terminals, wall plugs and ball fittings for electroliers, 30 per cent. ad val. (British goods 25 per cent.) if brass or gunmetal, and 17½ per cent. (British 10 per cent.) if of other material. Axles for steel-rimmed railway and tramway wheels of over 18 in. diameter 5 per cent. (British free), and steel-tyred wheels of over 18 in. diameter 35 per cent. (British 30 per cent.).

The Netherlands Minister of Finance has decreed that copper wire covered with varnished tape or tape prepared with paraffin is subject to an import duty of 5 per cent. ad val. Copper bands similarly covered and bright double-grooved copper wire for tramway overhead lines can be imported duty free.

Darwen.—Consumers who take 5,000 units of electric energy per quarter for power are to be supplied at ¾d. per unit.

Electric Driving of Mills.—A notable illustration of the value of public electric power supply has just occurred at Messrs. Rennie & Co.'s Providence Mills, Stanningley, where but for its aid the machinery would now be standing idle. On Wednesday last the main engine gave way, and the machinery brought to a standstill. Fortunately, the Yorkshire Electric Power Co.'s supply is available in Stanningley, and in 24 hours the supply was connected and the first motor set to work. By Sunday night the whole of the machinery was converted to electrical driving, and now over 400 H.P. is taken from the public mains. This is claimed to be a record.

Golborne.—The Board of Trade have decided to extend the period of the provisional electric lighting order (1905) for another year.

Greenock.—In moving the adoption of the minutes of the Electricity Committee on Tuesday, Bailie Williamson said that the demand for electricity had been so great that they had doubled their output at Dellingburn works during the past two years, and he believed that soon they would have to instal another additional turbine.

Haslingden.—An inquiry was held last week into the Council's application for sanction to borrow £8,750 for electricity supply.

At present the Council take electric current in bulk from Accrington, but the agreement with Accrington terminates in December, 1912, and Haslingden will then supply current to their tramcars from their own distributing station.

Holborn (London).—The matter of the improved lighting of the borough came before the Council last week, when the Town Clerk reported that he had received a sealed packet endorsed by both the Metropolitan Electric Supply and the Gas Light & Coke Companies, and thought it best to bring the matter before the Council before proceeding further.

The Town Clerk opened the package and read a letter dated from the Gas Light & Coke Co.'s offices. This was to the effect that the decision of the Council to request both the gas and the electric light companies to again tender for the lighting of the borough, after the figures of the previous tenders had been made public, and the fact that certain clauses in the new specification were onerous, had made it necessary for the companies concerned to confer together. After careful consideration they had decided not to quote in competition, but to submit a joint tender for the lighting of the borough partly by gas and partly by electricity for an inclusive annual sum of £6,950, a sum less than the amount of the tender recommended for acceptance in February last. A schedule and map were enclosed. The tender was to be based on a 10 years' contract terminable at shorter periods on payment of certain specified capital charges. The Council's requirement that the lamps should be maintained at the highest degree of efficiency was not to be complied with under the tender, but if it was desired that such an efficiency should be maintained the amount of the tender would be increased by 10 per cent nor could improved burners, lamps or appliances be adopted unless the Council agreed to pay the extra cost entailed. It was pointed out that the amount of the tender was only slightly in excess of what the Council were at present paying, while the candle-power would be increased 17 per cent., and the borough would be provided with the best and latest improvements in both forms of illuminant. The letter was signed by Mr. E. Cunliffe Owen on behalf of the Metropolitan Electric Supply Co. (acting in conjunction with the Charing Cross, West End & City Electricity Supply Co. and the County of London Electric Supply Co.), and by Mr. H. Rayner on behalf of the Gas Light & Coke Co.

Mr. MAX CLARKE, chairman of the Works Committee, said the tender was quite out of order, as it did not carry out the specifications.

Mr. FITZROY DOLL moved that the tender be referred to the Works Committee for consideration and report.

Mr. E. ANGEL supported this on condition that the report from the Works Committee should come before the whole Council in committee, and not in open meeting.

Mr. J. S. MOTION said the tender they now had was only the natural result of the Council trying to ring the changes on the gas and the electric light companies.

After further discussion the motion to refer to the Works Committee the report to come up to a committee of the whole Council, was agreed to.

Holyrood Palace.—In preparation for the visit of the King and Queen in July this Palace is being improved and renovated, and the electric light is being installed.

Inquest.—An inquest was held at Blackpool on Wednesday last [illegible] death of Thos. Geo. Sidney, who was employed at the [illegible] electricity works, and who was killed on the 10th inst. [illegible] working on some repairs.

[illegible] ARMSTRONG, outside foreman of the electricity department (who [illegible] with Sidney), said the latter asked if there should be any [illegible] and he (the witness) replied, "No. If you get anything, it will [illegible] high-tension pressure." Sidney replied, "Well, I've got it, and [illegible] me sweat." Witness replied, "For God's sake don't touch it. [illegible] home the works and get it cleared." He thought there was [illegible] gage, and warned Sidney not to touch the wires unless he put [illegible] on. He then telephoned the works to take the current off, [illegible] found Sidney stretched on the flags unconscious. He tried [illegible] desperation and sent for a doctor, but Sidney was dead before [illegible] arrived. The pressure would be 2,000 to 3,000 volts.

W. E. DAGGER, public lighting superintendent, said he started the [illegible] and as he did not expect that it would keep them until [illegible] working hours he gave no notice at the works for the [illegible] lamps to be kept clear. When men worked overtime it was [illegible] gave notice at the works to that effect. He did not dream that [illegible] be any overtime. Such an accident had not previously [illegible] his experience.

[illegible] returned a verdict of death from misadventure.

[illegible] GRAINGER expressed sympathy with Dagger, and said he hoped [illegible] consequences to himself would result from the sad occurrence. [illegible] was carefully conducted, and he hoped the Corporation would [illegible] severely upon the accident.

Kingswood.—The Council have informed Kingswood Electric [illegible] Co. that they cannot permit the use of overhead wires for [illegible] electric current.

Lowestoft.—Application has been made to the L.G. Board for [illegible] loan of £3,000 for new mains.

[illegible] are lamps are to be substituted for the lamps in use [illegible] thoroughfares.

Malvern.—At a recent meeting of ratepayers a resolution was [illegible] expressing approval of the proposal to establish a system of [illegible] in Malvern, and calling upon the Council to sup- [illegible] promotion of the bill now before Parliament.

Manchester.—At Tuesday's meeting of the Tramways Committee [illegible] reported that the income for the past year was estimated at [illegible] against the earlier estimate of £809,688), of which it is cal- [illegible] will come from the parcels department.

[illegible] committee decided to hand over in relief of rates £75,000, the [illegible] contributed last year, and to apportion £4,100 to the [illegible] purchase interest.

[illegible] Committee have decided to start a new system of con- [illegible] the city fund, and the payments now and in future years will [illegible] at 1 per cent. on the outstanding indebtedness of the under- [illegible] The amount to be allocated this year is £19,496, against £15,000 [illegible]

[illegible] reported that the Easter week-end tramway traffic results [illegible] figures. The week's receipts were £16,603, against £14,843. [illegible] carried 3,330,893, against 3,108,675.

Post Office and Telephone Control.—At the annual Conference [illegible] National Federation of Sub-postmasters at Cardiff on [illegible] Postmaster-General (Mr. H. Samuel) said :—

[illegible] to be in the future further development in the work of [illegible] when the National Telephone Co.'s system was taken over, [illegible] prospects, as that business developed in the future, many [illegible] Post Office staff would find their activities enlarged and [illegible] almost proportionately increased. He had observed that [illegible] of Commerce had suggested as a matter of inquiry [illegible] telephones instead of being transferred to the Post Office [illegible] transferred to a Telephone Authority created for the pur- [illegible] of representatives of the local authorities, of commerce [illegible] If some such scheme were in the public interest he [illegible] it, for although it was detrimental to some hopes [illegible] vested in the Post Office, the public interest must be [illegible] Telephone Authority which had lately been discussed [illegible] his mind every possible disadvantage, and could offer [illegible] compared with the direct control of the system by [illegible] Department. It would involve the loss of millions of [illegible] the Post Office system of poles and underground [illegible] used jointly for telephones and telephones. It would [illegible] entirely for new buildings, and a more unbusinesslike [illegible] have been put forward by those who claimed to repre- [illegible] interest. That authority would not be under any control, [illegible] of its own. Complaints might be attended to or [illegible] to him that a great national service could not be [illegible] than the direct supervision of the House of Com- [illegible] had lately been collecting information regarding the [illegible] in the United States, Sweden and other countries [illegible] system had been widely developed, and he had every [illegible] the present system of telephones in this country [illegible] the best in any other country. Many improve- [illegible] in the system in recent years and others would follow. He had no doubt that the telephone system of the United Kingdom under the able supervision of the Post Office would be equal to any to be found in any quarter of the world.

At the annual conference of the Amalgamated Society of Telephone Employés, which was held at Leeds last week, many questions affecting the status of telephone workers, &c., were discussed.

The Society are to take steps to safeguard their continued existence after the transfer, and the Post Office authorities are to be asked to give information relative to the proposed conditions of service, also as to the grades into which the various ranks will be placed. The executive of the Society are to seek to secure the removal of educational, technical and theoretical examinations as a condition of promotion subsequent to the transfer. Questions of classification, pay, &c., were debated and resolutions passed.

Rawtenstall.—An unopposed inquiry was held last week into the Council's application for sanction to borrow £15,000 for extensions of the electricity undertaking.

Rubber Exhibition.—An International Rubber and Allied Trades Exhibition will be held at the Agricultural Hall (Islington, London, N.) from June 26 to July 14 inclusive. The Exhibition is being organised by the International Rubber and Allied Trades Exhibition, 75, Chancery-lane, W.C.

St. Pancras (London).—The chief electrical engineer (Mr. S. W. Baynes) recently reported on the working of the generating stations, and made certain recommendations, which have been approved by the Electricity Committee.

In future the whole of the load during 10 hours of the day is to be taken by the King's-road station, and three-phase mains are to be laid between the two stations. Only one main is to be laid now, but a four-main capacity duct will be provided, so that additional mains can be drawn in as required in future. The cost of the main and ducts is put at £3,100, and it is calculated that a saving of at least £1,300 per annum will be effected.

Shoreditch (London).—The town clerk (Dr. H. Mansfield Robinson) has resigned, in order to take up the position of clerk to the Income Tax and Land Tax Commissioners for the Tower Division. Dr. Robinson has been 20 years at Shoreditch, and during this period many improvements have been effected in the borough, including the introduction of electricity supply. He took a keen interest in the development of electricity supply in London, and he was joint secretary (with Mr. H. B. Renwick) of the Consultative Committee of the Joint Conference of the London Electric Supply Authorities which is dealing with the linking-up of electricity supply undertakings.

Stockton-on-Tees.—The Council have agreed to supply electricity to Messrs. Head, Wrightson & Co. for the Stockton Forge for five years at $\frac{11}{16}$d. per unit for the first two years, and at $\frac{3}{4}$d. per unit for the remaining three years, with a minimum payment of £500 per annum.

It was reported to the Council that the continuance of the supply of current to the firm would entail an expenditure of £5,000, and the firm have the option of increasing the amount of electricity to be supplied from 200 kw. to 250 kw.

Swanage.—The Council have refused the offer of Mr. F. Swarbrick to prepare an electricity supply scheme for the district.

Swindon.—The Council have applied for sanction to a loan of £3,510 for a new storage battery, &c.

Truro.—The General Purposes Committee are considering communications from Messrs. J. B. Saunders & Co. and Mr. F. Swarbrick in regard to electricity supply schemes.

West Ham.—The Council are recommended to carry out the following works, at a cost of £8,925 :—

(*a*) Extension of the d.c. cables and installation of rotary converters. (*b*) Extension of feeder cable at a cost of £1,400, and extension of return cable at a cost of £1,425.

Whitehaven.—An honorarium of £50 has been granted to the borough electrical engineer (Mr. P. B. Sankey) for services in connection with the extension of the plant at the electricity works.

Will.—Mr. James Graves, Atlantic Villa, Valencia Island, co. Kerry, Ireland, who was one of the oldest members of the submarine cable service, and until recently in the service of the Anglo-American Co., left personal estate amounting to £8,557.

Wireless Telegraph Notes.—The Canadian Minister of Marine has again introduced into the Dominion Parliament a bill for the compulsory carrying of wireless telegraph installations by all passenger ships trading from Canadian ports and carrying 50 or more passengers.

When the British Imperial Conference meets next month in London the New Zealand representative will, it is stated, move a resolution certifying the great importance of radio-telegraphy "for social, commercial and defensive purposes," and propose that a chain of State-owned wireless telegraph stations be established throughout the British Empire.

Digitized by Google

"Electra" Musical Society.—This Society will give a ladies' bohemian concert in the Small Queen's Hall, Langham-place, London, W., on Monday next (April 24), when the chair will be taken at 7:45 by Mr. J. C. Denison-Pender, L.C.C. Tickets and all further particulars can be obtained from the hon. sec., Mr. G. H. Goldsbrough, Electra House, Finsbury-pavement. E.C.

COLONIAL AND FOREIGN NOTES.

Argentina.—Señor M. Tourville has secured a concession for the erection and working of a telephone line from Misioneros (Santa Cruz) and Paso (on the Santa Cruz river).

Australasia.—The "Australian Mining Standard" says Kyneton (Victoria) Shire Council have referred to a committee a report and estimate on a proposal that the Council should establish an electricity supply undertaking. Two water-power schemes have been rejected, and a third, which is still under consideration, includes the use of a suction gas plant and overhead mains, the initial capital expenditure being put at £4,011.

Mr. G. B. Lincolne has also recommended Gea (Victoria) Council to adopt an electric lighting and pumping scheme.

Mortlake (Victoria) Butter Factory Co. recently applied to the Supreme Court for an alteration of their articles of association to enable them to supply electricity to private consumers and for public lighting. The application was adjourned.

Petersburg (S. Australia) Council recently interviewed Mr. Moncrieff (Railways Commissioner) upon a proposal that the Council should take a supply of electrical energy for lighting the town from plant which is being installed in the locomotive workshops.

Yarrawanga (Victoria) Shire Council recently issued £3,500 debentures to finance their proposed electricity undertaking.

The conference of representatives of Australian tramway employés has completed its log of wages and working conditions. It is proposed that eight hours shall constitute a day's work, that all employés shall be guaranteed 48 hours work per week, every motorman and conductor to have one day off in seven. Not more than 10 per cent. of the men to be employed on broken shifts, and these must not extend over 10 hours, the pay per day to be as follows: Motormen and conductors 11s., ditto, probationers 9s., ticket examiners 12s., shed foremen, 13s., ditto assistant 10s., electrical foreman 16s. 6d., electrical fitter foreman, 15s., electrical mechanics 12s. 6d., controller men 10s., switchboard attendants 10s., car and motor cleaners 9s., overhead wiremen 12s., and 12s. 6d., engine drivers in power house 15s., firemen 11s., coal conveyor attendants 11s., general labourers 10s., truck cleaners 9s. Sundays and statutory and proclaimed holidays, if worked, are to be paid for at double rates, and all employés with over 12 months' service are to have 21 days' leave per annum on full pay. The following resolution of the conference has been accepted by a majority of the men's association: "That no member of the association be compelled to work on or about any road upon or in connection with which a non-member of the association is employed, and he shall not be expected to handle any power that has been generated, produced or handled by a non-member. No employé shall be requested to mount any car that has been repaired or examined by a non-member."

It is stated that Mr. Reginald P. Wilson, who is associated with Mr. Merz, arrived in Melbourne recently and discussed with the Victorian Railway Commissioners the report submitted to them by Mr. Merz some time ago on the proposed electrification of the Melbourne suburban railways. Mr. Wilson said the report was unduly conservative in comparing the d.c. and a.c. systems on account of improvements likely to be made in the latter, but the improvements since made had been in favour of the former. However, they recommended the direct current not on the ground of greater efficiency but because the interest and sinking fund charges would be less.

Shepparton (Victoria) Shire Council have joined the Urban Water Works Trust in defraying the cost of a report on a scheme for electricity supply in Shepparton.

Gawler (S. Australia) Council recently decided to submit to the Minister for approval a scheme prepared by Mr. Lincolne for the erection and equipment of electricity works for the town, at a cost of about £4,000.

Hastings (N.Z.) Council are recommended to invite offers for the construction of a tramway and then to take a poll of the ratepayers as to whether any offer be accepted, or whether the line be constructed by the municipality.

Palmerston (N.Z.) Council are to obtain a report on Mr. Edison's traction battery to enable them to decide whether such battery cars can be advantageously used on the electric tramways which it is proposed to construct in the borough as a cost of £61,000.

Wanganui (N.Z.) Council, who supply electrical energy for the Castlecliff tramways, recently decided to extend their power station plant and to invite tenders. Motors for the new cars are of 40 H.P.

Daylesford (Victoria) Council are having plans and estimate of cost of electric lighting plant prepared. The Daylesford Gas Co. is being wound up.

The "Mining and Engineering Review" (Sydney and Melbourne) says that Annandale Council, who have been paying the Australian Gaslight Co. £672 a year for street lighting (300 nights per annum) by 158 gas lamps, have now entered into an agreement for the electric lighting of the streets by Sydney City Council (every night in the year) by 173 lamps at £654. 7s. 6d. per annum.

The inauguartion of the Ballina (N.S.W.) electric lighting system took place recently. There are 64 street lamps varying from 32 to 200 c.p.

Plans and specifications were recently prepared for electric lighting and pumping plant for Swan Hill (Victoria). Mr. A. H. Wood is consulting engineer.

Bolivia.—A German Consul suggests that a good opportunity exists for the provision of electricity works at the town of Riveralta, the population of which has doubled in the last three years and is still growing.

Canada.—At the offices of the High Commissioner for the Dominion of Canada, 17, Victoria-street, London, S.W., the names can be obtained of Vancouver and Ottawa correspondents who wish to get into communication with British manufacturers of electrical fittings, carbon and tungsten lamps, porcelain goods, electric generators, motors, instruments, small transformers and watt-hour meters.

The Toronto Electric Light Co. have declined the offer of the City Council to purchase their undertaking, but they have agreed to sell to Sir Wm. Mackenzie.

Cuba.—A Canadian company has secured a concession for the erection of an electric light and power station at Cienfuegos.

Holland.—It is proposed to establish electricity works for the province of Groningen, and one scheme, estimated to cost about £104,000, includes the erection of a power station at the town of Groningen. New electric tramways in the province are projected and also the electrification of the line from Groningen to Zuidbroek and, subsequently, the continuation of the electrification to Wildervank.

Street Lighting in Budapest.—Mr. Etienne de Fodor, general manager of the Budapest General Electric Co., has received a further order from the Municipal Council of Budapest to erect and install additional street arc lamps. In 1909 Mr. De Fodor put up a trial plant with flame Alba arcs in one of the principal streets at the company's expense, the object being to show what modern lighting was. The results were so gratifying that the Council not only took over the entire trial plant but ordered some 160 further arcs to be placed in other thoroughfares in 1910. Since that time the city authorities have taken over the whole company, and have been trying experiments with high-pressure gas lights but the results obtained (we are informed by a correspondent) have by no means proved so favourable as those given by the flame arc, consequently the municipality has decided to erect 380 more this year, all the principal thoroughfares of Budapest being illuminated by electric arc lights. The arc lamps are of the Siemens Schuckert "Alba" type with vertical carbons, and are connected three in series on a 110-volt circuit, taking 15 amperes. The lamps are mounted on ornamental iron posts which are placed at about 50-metre distances from one another on one side of the street, the diagonal distance between lamps on the opposite side of the street being about 35 metres. The distance of the arc to the level of the street is about 9 metres. A typical Budapest thoroughfare is shown in the illustration above.

A BUDAPEST THOROUGHFARE, SHOWING TYPE OF ARC LAMP USED.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS invite tenders (from manufacturers) for supply of opal lamp shades during three years. Forms of tender, conditions of contract and particulars from the Storekeeper, H.M. Office of Works' Stores, Lambeth Palace-road, London, S.E. Tenders by 11 a.m. on Wednesday, May 10, to the Secretary, H.M. Office of Works, Storey's Gate, S.W. See also an advertisement.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS want tenders (from manufacturers) by 11 a.m., Friday, May 5 for supply of electric gas torches during one year. Forms of tender from the Storekeeper, 12, Lambeth Palace-road, London, S.E. See also an advertisement.

Digitized by Google

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

The Corporation of HASLINGDEN invite tenders for supply and laying of extra high pressure trunk mains, with medium pressure feeder and distribution cables. Specification, drawings, form of tender, &c., from the engineer, Mr. S. J. Watson, M.I.E.E., Electricity Works, Bury. Tenders to Mr. W. Musgrave, town clerk, Haslingden, by noon Friday, May 5. See also advertisement.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z. until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, engine-room crane, circulating pumps and pipes and switchboard. Specifications and drawings at the offices of the High Commissioner for the Dominion of New Zealand, 13, Victoria-street, London, S.W. See also an advertisement.

The COMMISSIONERS of H.M. WORKS AND PUBLIC BUILDINGS also invite tenders (from manufacturers) by 11 a.m. of April 28, for the supply of carbon and metal filament lamps for one year from May 1911. Form of tender, conditions of contract, &c., from the Storekeeper, 12, Lambeth Palace-road, London, S.E. See also an advertisement.

Tenders are invited up to May 30 for the supply of one portable steam-driven desiccating plant to the Postmaster-General's department in Victoria, and up to May 31 for the supply of 7,000 insulators and spindles and line material to the Postmaster-General's department in SOUTH AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisements.

The EGHAM & DISTRICT ELECTRIC LIGHT CO. (LTD.) invite tenders for supply of two high-speed Diesel oil engines, coupled to two 100 kw. three-phase alternators, with direct-coupled exciters, piping, tanks and accessories; one 4-ton overhead traveller and main h.t. switchgear. Tenders to the secretary (Mr. H. T. Manwaring), 53, Cannon-street, London, E.C., by noon, April 24.

The PANCRAS (London) Borough Council invite tenders for three-core h.t. cable and for stoneware ducts. Copies of specification, conditions of contract and form of tender from the Electricity Department, Offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk, Mr. C. H. F. Barrett, Town Hall, Pancras-road, N.W., by noon, May 15.

The DERBY Corporation invite tenders for supply of inverted rotary converters, h.t. cable and switchgear. Specifications and forms of tender from the borough electrical engineer, Mr. T. P. Wilmshurst, St. Mary's-gate, Derby.

The FULHAM (London) Borough Council invite tenders for the supply, delivery and erection of a 1,500 kw. turbo-alternator with condensing plant. Tenders by noon, April 26, to the town clerk, Mr. J. Percy Boulton, Town Hall, Fulham, S.W.

The GLASGOW Corporation invite tenders for supply and erection of a 5,000 kw. turbo-alternator, with condensing plant for Pinkston generating station. Tenders to town clerk, Mr. A. W. Myles, City-chambers, Glasgow, by 10 a.m. April 24.

HORNSEY Town Council require tenders by 4 p.m. April 24 for supply and erection of flame arc lamps. Forms of tender, &c., from the Borough Electrical Engineer.

WALTHAMSTOW Council want tenders by 5 p.m. April 28 for a cooling tower and switchboard extension (two panels). Specifications &c., from Mr. G. R. Spurr, Electricity Works, Walthamstow.

SALFORD Corporation require tenders by 10 a.m. April 24 for the supply and erection of fire and police alarm street boxes and switchboard. Particulars from the Chief Constable.

WORTHING Corporation require tenders by noon April 24 for replating storage battery. Specifications, &c., from the Borough Electrical Engineer.

ILFORD Council require tenders by noon May 9 for the supply of distributing switchboard, feeder cable and stoneware conduits. Specifications, &c., from Mr. A. H. Shaw, Electricity Works, Ley-street, Ilford.

BARNES Council require tenders by noon May 9 for the supply and erection of combination de-oiling, softening and feed heating plant. Specification, &c., from the Engineer, Electricity Works, Mortlake.

ALDERSHOT Council require tenders by May 2 for replating batteries. Particulars from the Electrical Engineer, Laburnum-road, Aldershot.

COLWYN BAY and COLWYN COUNCIL require tenders by May 3 for one year's supply of cables and accessories, engine room stores and prepayment and ordinary meters. Forms of tender from the Clerk.

SOUTH SHIELDS Corporation want tenders by May 24 for supply and erection of 1,500 kw. high-pressure steam turbine (with surface condenser and pumps) coupled to 1,000 kw. d.c. generator (with switch panel, &c.) and 1,100 kw. a.c. generator (with switch panel, &c.). Specification, &c., from the Borough Electrical Engineer.

LUTON Corporation want tenders by 7 p.m. April 24 for supply and erection of turbine generators, condensing plant, and cooling tower. Specifications, &c., from the Borough Electrical Engineer.

Tenders are also invited by the MELBOURNE City Council for the supply, delivery and erection of a battery of accumulators with boosters and switchboards. The battery is to be capable of daily maintaining a normal capacity of 4,000 amperes for one hour, during which discharge the voltage of each cell shall not be lower than 1·7, the number of cells to be sufficient to maintain a total voltage across the whole battery of 475 volts at any time during discharge at the one-hour rate. Tenders are also invited for three years' maintenance. Tender forms, &c., from Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by noon May 8.

Tenders are invited up to May 16 for the supply of 10,000 protectors for use at subscribers' telephone stations; up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c.; and up to June 14 for supply of a branching multiple magneto lamp signalling switchboard at Ballarat, for the Postmaster-General's Department in VICTORIA; and up to June 14 for supply of a c.b. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA. Tender forms, &c., from 72, Victoria-street London, S.W.

The Director of the Municipal electricity works, NAGYVÁRAD (Hungary), will receive tenders until April 29 for supply of a 1,800 H.P. steam turbine, a three-phase 3,000-volt generator, with condenser, switchboard, &c., and two boilers. The amount provided to cover the expenditure is £17,000.

Extension of Time.—The date for receiving tenders for the erection and equipment of electricity works at VARNA (Bulgaria) (see p. 35 of our last issue) is extended to May 18.

TENDERS RECEIVED AND ACCEPTED.

Colchester Corporation have accepted the following tenders for annual stores:—

Joslins (Ltd.), ironmongery car fittings, oils and grease; Brackett & Co., castings, &c.; Cammell, Laird & Co., wheel tyres; and Watlington & Co., overhead equipment for the tramways department, Stanford & Co., castings; A. E. Diss & Son, joiner's work; Joslins (Ltd.), prepayment meter installations, ironmongery and tools, oilman's and sundries and castor oil; W. Lucy & Co., fuse boxes; and Venner & Co., prepayment and ordinary meters, for the electricity department.

Wrexham Corporation have accepted the following tenders for annual stores:—

British Insulated & Helsby Cables, service cutouts; General Electric Co., arc lamp carbons; Dussek Bitumen Co., bitumen and box compound; James Light & Sons, crank chamber oil; Henry Wells Oil Co., cylinder oil, lubricating oils; Barton & Co., coal; E. Wade Wilton, boiler

Digitized by Google

solution; no tenders have been accepted for cables, meters or incandescent lamps.

Sydney City Council (N.S.W.) have accepted the following tenders:—

Siemens Bros. Dynamo Works, arc lamp carbons, £3,909. 9s. 8d.; W. T. Glover & Co., cable suspenders, £117. 10s., and insulators, £125; Wm. Adams & Co., Nobel's turbine oil, 3s. 3d. per gallon; and Noyes Bros., Haes & Eggers, Siemens Bros. & Co., India Rubber, Gutta Percha & Telegraph Works Co., Australian General Electric Co., Lawrence & Hanson, Paton & Co. and W. G. Watson & Co., for annual supplies of electrical accessories.

Partick Council have accepted the following tenders for stores:—

W. C. Yuille & Co., engine room stores, tools and ironmongery; General Electric Co., cable jointing requirements, service cutouts and lamps; W. T. Henley's Telegraph Works Co., service cutouts; Chamberlain & Hookham and Ferranti Limited, meters; Sloan Electrical Co., arc lamp carbons; Valvoline Oil Co., oils (six months); and Robinson, Dunn & Co., wood troughing.

Southampton Council have accepted the following tenders for annual supplies to the tramways department:—

British Thomson-Houston Co., lamps; Lankester & Son, screws and files; Ralph Harris, iron and steel; Armstrong, Stevens & Son, bolts and nuts; McWhirter, Roberts & Co., nails, &c.; Flack, Ellis & Co., castings; Edk. Bird & Co., tools.

Stoke Corporation have accepted the tender of Jas. Howden & Co., at £8,905, for supply and erection of two three-phase 1,500-1,750 kw. steam turbo-alternators, 6,600 volts, 50 cycles (Siemens' alternators and exciters), regulating resistances, Tirrill regulator, Mirrlees Watson condensers and motors.

Norwich Corporation have accepted the following tenders:—

Premier Accumulator Co., supply and erection of a storage battery at £3,415, and for maintaining same for 10 years at £205 per annum; Lancashire Dynamo & Motor Co., battery booster, regulator and switchboard at £704; and Crompton & Co., balancer with switchgear, mounted on an iron kiosk at £155.

Walsall Council have placed an order with the Equipment & Engineering Co. for ½ mile of single trolley wire, at 9d. per pound. The tender of Alfred Hall for supplying and fixing an armature drying stove, together with armature trolley to carry two armatures, at £18, has been accepted.

Kensington (London) Council have accepted the tender of J. Defries & Son (at £425) for the illumination and decoration of the public buildings at the Coronation.

Westminster City Council have accepted the tender of Speedy, Enyon & Co. for the electrical illumination of portions of Piccadilly at the Coronation, for £1,000 including supply of current.

Gravesend Council have accepted the tender of the Electrical Apparatus Co. for small meters, and those of Ferranti Limited and the British Thomson-Houston Co. for large meters.

The Chloride Electrical Storage Co. have obtained the contract for 270 1,200-ampere-hour cells and 270 2,400-ampere-hour cells for the Darlinghurst and Burwood (Sydney) tramways sub-stations.

West Ham Corporation have accepted the tender of Hadfield's Steel Foundry Co. for 200 steel tramcar wheels.

Cheltenham Council have placed an order with the Phœnix Dynamo Mfg. Co. for a motor generator, at £537. 10s.

Southend Council have placed an order with the North Eastern Steel Co. for 650 to 750 tons of Sandberg tram rails, at £6. 10s. per ton.

Newport (Mon.) Council have accepted the tender of R. Alger & Sons for wiring the higher elementary schools for £488.

Wakefield Council have placed an order with McPhail & Simpson for three superheaters, at £360.

Commonwealth Contracts.—The Australian Postmaster-General's Department have accepted the following tenders:—

New South Wales.—R. Johnson, Clapham & Morris, h.d. copper wire and copper tapers; T. Zwicker & Co., jointing sleeves and porcelain insulators; Lawrence & Hanson Electrical Co., iron spindles for cross arms; F. Lassetter & Co., bolts.

Victoria.—Western Electric Co., two and five-conductor cords iron-clad indicators, listening and ringing keys, polechangers, plugs, magneto switchboards, &c.; British Insulated & Helsby Cables, three-conductor cords, induction coils, micro-telephones, watch pattern receivers and relays; R. Johnson, Clapham & Morris, g.i. wire; Gibbs, Bright & Co., lead-covered paper insulated telephone cable.

South Australia.—Western Electric Co., silk and cotton insulated and light lead covered switchboard cable; Gibbs, Bright & Co., paper insulated lead covered cable; India Rubber, Gutta Percha & Telegraph Works Co., copper binders and insulators; W. G. Watson & Co., porcelain insulators.

Queensland.—J. F. Lambert, supply and erection of copper wires on existing poles from Cairns to Marsuba.

Western Australia.—J. Bartram & Son, magneto bells, micro-telephones, switches, handles and portable telephones; British General Electric Co., oiled paper condensers, microphone mouthpieces, Leclanche zincs and insulated tinned copper; British Insulated & HelsbyCables, v.i.r. copper conductor lead-covered cable, switchboard cable, two-twisted conductor rubber insulated braided wire and h.d. copper wire; India Rubber, Gutta Percha & Telegraph Works Co., condensers, Varley galvanometers, detectors, lightning arresters, P.O. pattern polar relays, rheostats, sounders, transmitters, keys, pole changers, switches, &c.; Western Electric Co., coin attachments, twisted pair outside wire, insulators, &c.; Siemens Bros. Dynamo Works, tubular iron poles; W. T. Henley's Telegraph Works Co., lead-covered paper-insulated cable and tinned copper r.i. cotton covered and braided wire; R. Johnson, Clapham & Morris, g.i. wire; T. Zwicker & Co., sulp. of magnesia; Unbehaun & Johnston, desicating apparatus with motor-driven air pump; Noyes Bros., tinned copper v.i.r. insulated taped and braided wire and gal. steel wire; General Electric Eng. Co., single bridle wire; Wright & Gibbs, manhole covers and frames; Tomlinson Bros., manhole plates; Saunders & Stuart, rolled steel beams; Geo. Wills & Co., bronze wire.

New South Wales.—The Harbours and Water Supply Branch have accepted the tender of Noyes Bros. for a hydro-electric generator, transmission line and pumps for water supply of towns north of Wollongong, at £1,820. 6s. 8d.

The Victoria Minister for Mines (the Hon. P. McBride) has accepted the tender of Thompson & Co., of Castlemaine (Victoria) for boilers for the electric plant for Wonthaggi (Victoria) States Coal Mine. Eight tenders were received, five for Australian made Lancashire boilers and three for imported boilers. The latter were for Babcock & Wilcox, Bettington, and Wolf boilers. The amount of the accepted tender, which includes the supply of five new Lancashire boilers and the erection of three boilers for the Government and fitting the whole eight boilers with superheaters and underfeed stokers, is £9,492. 17s. The total cost of installing the steam raising plant, including boiler room, smoke stacks, steam piping, feed piping, feed pumps, &c., will be £14,792. 17s. Imported boilers could have been installed at a total cost of £11,061.

Turbine Contracts.—During the past three weeks Messrs. Jens Orten-Böving & Co. have received a number of orders, including:—

Ushino Kubi, two Francis turbines, each of 1,300 H.P. under a head of 80 ft. Two Francis turbines each of 90 H.P. under a head of 30 ft. for Council of Taihape (N.Z.); one Francis turbine of 60 H.P. under a head of 4½ ft., for Messrs. Christy Bros. (Chelmsford); one Böving patent water turbine governor, for Shibaura Engineering Works, Japan; one Francis turbine of 14·4 H.P., under a head of 61 ft. 6 in., at 900 revs. per min., complete with governor, for University of Liverpool. Also one Victoria turbo-pump, to deliver 450 gallons per minute against a head of 205 ft., for Furukawa Ani Mines, Japan; and one pump to deliver 350 gallons per minute, against 555 ft. head for the Johnsonville (N.Z.), &c.

BUSINESS NOTICES.

Messrs. Donovan & Co. have removed to 47, Cornwall-street, Birmingham, where they have started a special conduit and fittings department. Telephone numbers 5,703 and 5,704.

The Midland Electric Mfg. Co. are removing their factory to Stafford Works, Rea-street South, Birmingham.

Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell will include in their sale by auction at H.M. Dockyard, Chatham, on Tuesday, May 9, and following days, 210 tons scrap brass and mixed metal, 27 tons white metal, 28 tons manganese and phosphor bronze, 800 tons mild scrap steel, 500 tons wrought and c.i. scrap, 100 tons steel wire rope, 76 tons lead and zinc ashes and bottoms, 30 tons electric cable, electrical gear and stores, two dynamos, 12 old engines, machine tools, &c. May be viewed three days prior to and on mornings of sale, and catalogues (6d. each) had at the Dockyard, or of the Auctioneers, 11, Billiter-square, London, E.C. Further particulars are given in an advertisement.

Patents Development.—The proprietor of letters patent No. 5,187.1907, relating to "The distance transmission of photographs, &c.," desires to licence British manufacturers to work same in Great Britain. Applications to messrs. Boult, Wade & Tennant, patent agents, 111 and 112, Hatton-garden, London, E.C.

The proprietor of letters patent No. 12,326/1908, for "Dynamo electric machines," desires to license British manufacturers to work the invention in Great Britain. Applications to Messrs. Boult, Wade & Tennant, Patent Agents, 111 and 112, Hatton-garden, London, E.C.

Plant for Sale.—Elektron Limited (in liq.), Gothenburg, offer for sale triple expansion engines, c.c. dynamos, &c. Further particulars are given in advertisements.

Correction.—In the page advertisement of Messrs. Siemens Bros. Dynamo Works last week our readers were referred to the "Electrical Times" for "reason 3." In a number of copies the figure 3

Digitized by Google

was dropped in error, the type having fallen below printing level. Readers with imperfect copies will note that it was the figure 3 which should have appeared.

Reid's Colliery Guide.—Any publication which enables members of the electrical industry to come into contact with mining interests is welcome, and the "Handy Colliery Guide and Directory," for the counties of Northumberland, Durham and Yorkshire, for which Messrs. Andrew Reid & Co., of Newcastle-on-Tyne and London, are responsible, is a serviceable publication in this connection. Besides containing a useful map of the districts with which the guide is chiefly concerned, there are lists of collieries, colliery owners, agents, managers and engineers in all three counties; lists of associations and institutions connected with these counties, names and addresses of the inspectors of mines for the districts, and, in addition, an exceptional list of mine inspectors covering the entire United Kingdom. Various Acts of Parliament and Home Office and other orders affecting mining operations are also given, together with numerous items which one would expect to find in such a work. The price of the guide is 2s. 6d., and it is strongly bound and of a size that can be carried in the coat pocket.

BANKRUPTCIES, LIQUIDATIONS, &c.

A dividend is to be paid to creditors of Ernest F. Jones, electrical engineer, &c., 132, York-road, West Hartlepool. Claims to Mr. D. Sinclair, North Eastern Bank Chambers, Stockton-on-Tees, by May 1.

An application for the discharge of Wm. H. Steed, electrical engineer, &c., 13, Stamford-street, Altrincham, will be heard at the Court House, Quay-street, Manchester, on May 22.

Claims against the Rosario Electric Co. (Ltd.) can be sent to Mr. H. E. Fothergill, 52, Moorgate-street, London, E.C., by May 30.

BOOKS RECEIVED.

Copies of the undermentioned works can be had from *The Electrician* office, post free (to any foreign station), on receipt of published price, adding 3d. for books published at 3s. or 5s., and 15 per cent. for books published nett. Add 10 per cent. for abroad or for heavy books.

"Mathematical and Physical Papers," Vol. V.: "Thermody Namics, Heat and Geological Physics, Molecular and Crystalline Theory, Electrodynamics." By Sir W. Thomson, Baron Kelvin. Arranged and edited by Sir J. Larmor. (Cambridge: University Press.) 18s.

"Dictionary of Electrical Engineering." Edited by H. M. Hobart. (London, 1910: The Gresham Publishing Co.) 35s. net.

"Transactions of the South African Institute of Electrical Engineers." Vol. I., part 14, and vol. II., part 1. 2s. each.

"Proceedings of the Royal Society of Edinburgh." Vol. XLVII. Session 1910-11. £1. 0s. 10d.

COMPANIES' MEETINGS AND REPORTS.

ANGLO ARGENTINE TRAMWAYS CO. (LTD.)—Mr. J. B. Concanon, who presided at the meeting last week, stated that the company carried 31,000,000 passengers in 1910. Gross receipts were £2,419,185, and net £855,092 (including £110,000 credited to depreciation renewals funds) showing a profit of £855,092. An interim dividend of 4 per cent. had been paid on the ordinary shares, and the directors recommended a final dividend of 4½ per cent., leaving £13,044 to be carried forward. Mr. Concanon also gave particulars of the present scheme for the construction of subways in the city.

BARNETT & WILCOX (LTD.)—The directors' report for the year ended Dec. 31, 1910, states that the net profit during the year amounted to £63,082, and with balance brought forward (£63,082. 14s. 9d.) £85,342 17s. 7d. Interim dividends of 3 per cent. on the preference shares, and 10 per cent. on the ordinary shares amounted to £86,000, leaving £85,342 17s. 7d. The directors recommend the following appropriations, viz.: 3 per cent. on the preference, less tax (£3,000), 20 per cent. on the ordinary shares, tax free (£66,400); also a bonus of 20 per cent. on the ordinary shares, tax free (£66,400). £100,000 has been written off, reserve (bringing this fund to £700,000), £25,000 to the depreciation fund, and £10,000 to staff pension fund, leaving £1,342 17s. 7d. to be carried forward. The volume of business during the year showed an increase, but competition and increased cost of materials reduced the ratio of profit. The turnover is, however, sufficient to give a good return on the capital, notwithstanding the reduced rates of profit on orders. The demand for the firm's specialities in naval work has been satisfactory, and their use in the mercantile marine continues to show progress, several important orders having been received in view of the application of crude oil engines for marine propulsion, the directors have acquired a general licence for the British Empire to use the patents and experience of the Maschinenfabrik Augsburg Nurnberg, a firm which has made the greatest advance so far in this direction. The firm are consequently in a position to take advantage of this development should the future require it.

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO. (LTD.)—Mr. F. E. Gripper stated at the recent meeting last the lamp connections had increased from 98,282 to 95,307 8 c.p. In spite of the introduction of metal filament lamps, the sale of current showed a slight increase. Including £172. 7s. 1d. brought forward the profit was £12,201. 18s. 3d. A final dividend at the rate of 8 per cent. (making 16 per cent. for the year) was declared.

CALCUTTA TRAMWAYS CO. (LTD.)—At the meeting on Wednesday the chairman (Mr. E. C. Morgan) said that they had run 40,000 car-miles and carried about 1,500,000 more passengers, producing an increase in traffic receipts of over £10,500. They had actually spent less money than in 1909. The savings had been effected by more careful supervision of expenditure. One of the most encouraging features in the report was the justification of the policy of the directors in carrying out extensions. It was agreeable to notice that the result of the last year's working showed a considerable increase in the profit, and he ventured to think that Howrah would soon be a welcome addition to their business, the ferry competition notwithstanding.

CHISWICK ELECTRICITY SUPPLY CORPN. (LTD.)—The directors' report for 1910 states that the undertakings at Chiswick and Aberystwyth continue to expand. £3,969 was spent on capital account for machinery, mains, free wiring, &c., while £263 was written off for depreciation. The number of consumers was 2,081, against 1,875 in 1909, and the revenue was £15,404, against £15,129, the profit for the year being £7,534, compared with £7,592. The results of the year's working enable payment of a dividend on the ordinary shares of 6 per cent., the same as paid for the previous four years. (The shares of the Chiswick Co. are held by the West London & Provincial Electric Supply Co., Ltd.)

CLAYTON & SHUTTLEWORTH (LTD.)—At the meeting last week Col. Frank Shuttleworth said that the question of their power supply had recently engaged the directors' attention. They were taking a considerable amount of electric power from the Lincoln city mains for general purposes, and for the sake of uniformity, and also because of the convenience and efficiency of the system, the board determined to adopt electric driving throughout the works. When they approached the Lincoln Electricity Committee on the matter they received an offer for an increased supply of power at rates sufficiently advantageous to warrant them entering into a new agreement with the Corporation. It was a tribute to the exceptional efficiency of that department of the Corporation that they had been placed in as favourable a position for obtaining cheap power as that enjoyed by concerns situated in the larger industrial centres of the country. It would be seen, therefore, that they were carrying out a well-ordered scheme of progress. Trade prospects continued to be favourable, and their engineering works were employed up to the limit of their capacity.

DEUTSCH-ATLANTISCHE TELEGRAPHENGESELLSCHAFT.—The directors' report for 1910 states that the profit, after meeting working expenses, is M.3,353,318 (£167,666), compared with M.2,966,311 (£148,316) in the previous year. Of this amount £7,195 has been placed to reserve, £20,000 to special reserve and repairs fund, £5,000 to insurance fund and £3,775 to pension and benevolent funds; £90,000 is devoted to payment of 7½ per cent. dividend, £6,476 for fees, &c., for directors and officials, and £25,222 is carried forward. The Atlantic traffic shows a steady upward tendency. The Vigo cable is so fully occupied that its duplication must be considered. With regard to the effect of wireless telegraph competition, the report states that since the opening of the Marconi Company's trans-Atlantic service the cable business has further increased. The spread of wireless telegraphy on ships and in out of the way islands has provided a new source of traffic for the cables.

GRASSINGTON ELECTRIC SUPPLY CO. (LTD.)—At a special meeting of shareholders last week it was decided to issue the remainder of the ordinary shares.

KIDDERMINSTER & DISTRICT ELECTRIC LIGHTING & TRACTION CO. (LTD.)—The report for 1910 states that the total capital expenditure to Dec. 31, 1910, on buildings and plant for electric supply amounted to £51,480. The gross receipts (including dividend on shares held in the Kidderminster and Stourport Electric Tramway Co.) amounted to £9,599, which, with £87 brought forward, made a total of £9,686, compared with £9,252 for 1909. After deducting expenses (including debenture stock and other interest), the available balance was £4,222. The directors propose to place £1,175 to depreciation and renewals fund, and £250 to debenture and loan redemption reserve. The cumulative preference dividend for the year absorbed £1,500, and it is proposed to pay a dividend at the rate of 2s per cent. per annum on the ordinary shares, leaving £122 to be carried forward.

LECHLADE ELECTRIC LIGHT & POWER CO. (LTD.)—The first annual meeting was held last week, when the chairman (Mr. B. F. Innocent) gave a resumé of the company's work since its inception, and said that in the face of difficulties it could now be said to be in a state of stability. The area of its usefulness was being slowly but surely extended.

ORIENTAL TELEPHONE & ELECTRIC CO. (LTD.)—Including £10,528. 12s. brought forward, and after deducting interim preference

Digitized by Google

and ordinary dividends of 3 per cent., and making provision for redemption of debenture stock and other charges, the amount to be dealt with is £37,065. 9s. 3d. The directors recommend payment of final preference dividend of 3 per cent. (less tax), and of 5 per cent. (tax free) on the ordinary shares (making 8 per cent. for the year). After making provision for reserve and for contemplated staff pension scheme, £18,099. 16s. 3d. is carried forward.

The Bombay Telephone Co. increased its dividend from 7 to 8 per cent., but the Telephone Co. of Egypt, the Bengal Telephone Co. and the China & Japan Telephone & Electric Co. continue to pay their previous rates (10, 5 and 5 per cent. respectively).

A 30 years' concession to extend the telephone service over the whole of the island of Mauritius where practicable has been granted to the company by the Government of Mauritius. The construction of the lines inland will commence as soon as the document is completed.

SAO PAULO TRAMWAY, LIGHT & POWER CO. (LTD.)—The gross earnings for 1910 were $2,949,292.90, operation expenses were $962,357.63 and net earnings $1,986,955.27. Deducting bond interest, taxes, &c., the net surplus was $1,003,093.19. $999,992.50 has been appropriated for dividends, $200,000 provided for renewals, &c., and $403,100.69 transferred to profit and loss. The gross earnings of the tramways amounted to $1,999,778.25, against $1,677,907.41. The gross earnings of the lighting department were $949,514.65, compared with $761,578.36. In addition to the regular expenditure for maintenance of property, there was expended in the renewal of different sections of track and overhead system, &c., $164,791.69. Expenditure on capital account during the year amounted to $1,051,819.17. The greater portion of this expenditure was incurred in installing for the hydraulic plant the third feeder pipe (12 ft. in diameter, 2,300 ft. in length), another 2,000 kw. generator, transformers and switchgear, a turbine, pen-stock, &c., and alterations and additions to plant for increasing the transmission-line voltage from 22,000 to 41,000 volts. The track mileage was increased by 2 miles, and additional feeders were laid for the light and power systems. In the company's shops 25 motor-cars were constructed and a sub-station was erected at Ypiranga. At Dec. 31 the equivalent of 75,900 8 c.p. lamps were connected, an increase of 12,031, or 18·8 per cent. Lighting customers were 5,343, increase 615, and power customers were 535, increase 107. Motors installed 1,159 (16,172 H.P.), increase 252 (4,384 H.P.).

SIR W. G. ARMSTRONG, WHITWORTH & CO. (LTD.)—At the recent meeting the Chairman (Sir Andrew Noble) said that although the results, both at Elswick and Openshaw, had been exceptionally good, the board did not think it desirable to increase the dividend beyond 10 per cent. They had carried forward sufficient to pay an additional 5 per cent., because they had found it necessary to remove their yard for the construction of war vessels from Elswick to a site below the bridge at Walker. The work in progress was considerably larger than at the corresponding period last year, and the position and outlook were satisfactory.

NEW COMPANIES, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

DRY GLASS ELECTRIC FIRE EXTINGUISHER CO. (LTD.) (115,216.)—Reg. on April 11, capital £1,000 in £1 shares, to carry on the business indicated by the title. Private company. Reg. office, 39, Corporation-street, Birmingham.

ELECTRICAL ENGINEERING & AGENCY CO. (LTD.) (115,089.)—Reg. April 4, capital £10,000 in £1 shares, to carry on the business of electricians, electrical and mechanical engineers, manufacturers of and dealers in electrical appliances, &c. Private company.

GEORGE BAILEY & SONS (LTD.) (114,974.)—Reg. March 29, capital £1,000 in £1 shares, to take over the business of an electrical, gas and general engineer, fitter and brass founder, carried on at Wolverhampton as G. Bailey & Sons. Private company. First directors: G. W. Bailey and Mrs. E. E. Bailey. Reg. office: 2, Berry-street, Wolverhampton.

INDESTRUCTIBLE ACCUMULATORS (LTD.) (115,259)—Reg. April 12, capital £12,000 in £1 shares, to carry on the business of engineers, manufacturers of accumulators, apparatus and engines, &c., and to adopt an agreement with the Vacuum Engineering Co. Private company.

PLAYER & MITCHELL (LTD.) (115,270.)—Reg. April 12, capital £15,000 in £1 shares, to take over the business of naval and railway brass-founders, lamp manufacturers, and electric lighting contractors carried on as Player & Mitchell, and to adopt an agreement with S. W. Mitchell. Private company. First directors, S. Sheppard and W. Dampier (both permanent). Reg. office, Attwood-passage, Cambridge-street, Birmingham.

STAIRWAYS (LTD.) (115,307)—Reg. April 13, capital £15 in 1s. shares, to carry on the business of makers, proprietors and conductors of electric and other lifts, stairways, elevators, escalators, moving stairways, tramways, railways and other mechanical appliances, &c. Private company. First directors, T. Kipping, S. Boyd and H. Hill (all permanent). Reg. office, 17, Gracechurch-street, London, E.C.

STANIAR, CLEGG & CO. (LTD.) (114,935.)—Reg. March 27, capital £1,000 in 500 10 per cent. preference shares of £1 each and 10,000 ordinary shares of 1s. each, to carry on the business of electrical engineers, dealers in electrical goods, cables, wires, dynamos, controllers, arc lamps, &c., and to adopt an agreement with H. D. Staniar and A. E. Clegg. Private company. First directors, H. D. Staniar and A. E. Clegg. Reg. office: 112, Portland-street, Manchester.

STATUTORY RETURNS.

CENTRAL ELECTRIC SUPPLY CO. (LTD.)—According to return to Feb. 4 capital is £100,000 in £5 shares. All shares taken up. £100,000 aid. Mortgages and charges, £450,000 guaranteed debenture stock.

COWPER-COLES INVENTIONS DEVELOPMENT CO. (LTD.)—Return to Dec. 31 gives capital £50,000 in £1 shares (25,000 A and 25,000 B, 1,582 A and 10,000 B shares taken up). £1 per share called up on 1,582 A and £1,582 paid. £10,000 considered as paid on 10,000 B. Mortgages and charges, £190 debentures.

DIRECT UNITED STATES CABLE CO. (LTD.)—In return dated Feb. 7 capital is £1,300,000 in £20 shares. 60,710 shares taken up. £1,214,200 paid. Mortgages and charges, nil.

KENT ELECTRIC POWER SYND. (LTD.)—According to return to Jan. 5 the capital is £15,030 in 1,500 ordinary shares of £10 each and 600 deferred shares of 1s. each. All shares taken up. £15,021. 14s. paid, leaving £8. 6s. in arrears. Mortgages and charges, £1,033.

MORTGAGES AND CHARGES.

HINDHEAD & DISTRICT ELECTRIC LIGHT CO. (LTD.)—Issue on June 11 of £50 debentures, part of a series of which particulars have already been filed.

NORTHAMPTON ELECTRIC LIGHT & POWER CO. (LTD.)—Memorandum of satisfaction in full on Jan. 13 of debentures dated March. 8, 1901, and March 29, 1906, securing £5,000 and £1,400 respectively, has been filed.

A. REYROLLE & CO. (LTD.)—Issue on March 30 of £600 debentures, part of a series of which particulars have already been filed.

RECEIVERSHIP.

J. C. CHILDS & CO. (LTD.)—Notice of appointment of H. W. Fresh water, 7-8, Railway-approach, London Bridge, S.E., as receiver, on March 31, under powers contained in debentures dated 1908, has been filed.

CITY NOTES.

NOTES.

The Institution of Electrical Engineers.

The following nominations for the new Council of the Institution of Electrical Engineers were announced at the meeting last night :—

President.
S. Z. de Ferranti.

Vice-Presidents.
Mr. W. A. J. O'Meara, C.M.G. W. Duddell, F.R.S.
J. F. Snell. W. H. Patchell.

Members of Council.
J. S. Highfield. G. K. B. Elphinstone.
[illegible] W. Judd.
E. T. Jenkin. P. V. McMahon.
[illegible] Kingsbury. R. K. Morcom.
[illegible] Sparks. W. M. Morrison.
W. A. Cook. S. L. Pearce.
[illegible] Dickinson. H. Faraday Proctor.
C. H. Wordingham.

Associate Members of Council.
H. F. Wimperis. E. Russell Clarke. S. Morse.

Honorary Treasurer.
Robert Hammond.

The names printed in italics are new nominations. The hon. treasurer retires annually, and is eligible for immediate re-election.

We are sure that our readers will note with sincere satisfaction the nomination of Mr. Ferranti to serve a second year as President of the Institution. So far as we are aware this is the first time that a President has served two consecutive years, and in setting such a precedent we think the Council have done well. The fact ought to have been realised ere this that the electrical industry is not sufficiently large to produce Presidents of the Institution at the average rate of one per annum. Even in the Institution of Civil Engineers, whose membership covers the whole field of engineering and is therefore much larger, it has been found desirable that the President should fill his office for two years, rather than for one. Election to the Presidency of the Institution of Electrical Engineers is the highest honour that the electrical industry can offer, and nothing will be lost by bestowing this honour less widely than has been the case in the past. We need say nothing of the claims of Mr. Ferranti to the position he now holds, for they are universally acknowledged.

As regard the new members of the Council, Mr. Highfield, Mr. Hirst, Mr. Kingsbury and Mr. Sparks have already been members at one time or another. Mr. Jenkin who is so well known in association with Sir Alexander Kennedy, has not previously served on the Council, and we are sure his assistance will be of value. New blood is always desirable on such bodies. Mr. Wimperis, the new associate member of the Council, is chiefly known to our readers for his work in connection with acceleration, gas engines and kindred problems. The name of Mr. Kingsbury will remind our readers of the controversy, marked by some unfortunate features, which took place when his election last year was opposed by an outside nomination. Although we are fully in accord with the view that the membership of the Institution in the provinces should be properly represented on the Council, we hope that any such contest will not occur on the present occasion. The Local Sections are at present exceedingly well represented, both by members elected to the Council and by *ex officio* members, and therefore we feel that the present nominations should be accepted as being in every way satisfactory.

Rail Corrugations.

Longer experience appears to assist but little in the solution of the problem of rail corrugation, which, for

Digitized by Google

several years now, has baffled tramway engineers. At one time it was hoped that a comparison of the experiences of different undertakings would provide a satisfactory explanation of the phenomenon, but the trouble has now become so widespread that this method of investigation seems likely to fail. Statistics of this nature have been collected for some years, and in view of the heavy expense that the removal of corrugations is likely to involve until some means is discovered of preventing their formation it is not surprising that tramway engineers are only too ready to place their experience at the disposal of the industry. Our contemporary, the "Tramway and Railway World," has from time to time collected valuable information on the subject. These statistics show that, whereas in February, 1907, 19 out of 57 municipal tramways in this country, from which particulars had been obtained, were immune from corrugation, two years later only 11 of these systems were unaffected; whilst at the present time only two undertakings—Dundee and West Bromwich—report entire absence of corrugations. At Bradford, however, there is practically none, and at Bolton only slight evidence of their formation. As these two undertakings have been in operation 12 and 10 years respectively the freedom from corrugation is noteworthy, particularly as the two most recent undertakings—those at Darlington and Gloucester, where corrugations were practically unknown a year or two ago—now report a considerable amount. At present there is no remedy but to grind out the corrugations as they become serious.

An interesting contribution to the subject has recently appeared in the "Electric Railway Journal" by Herr K. Sieber, of Nürnberg. His observations, which extend over many years, show, among other characteristics, that corrugations only appear when the speed exceeds a certain limit (depending on the track foundation), and their average length varies with the speed of the car; also that they do not appear on the treads of rails on short-radius curves, and that on curves of large radius the corrugations are deep and short on the outer rail and, if present on the inner rail, long and shallow. Although a short-radius curve is not defined, we believe that Herr Sieber's experience as to the absence of corrugations is not universal; but of more interest is his observation that, contrary to the statements of other engineers, corrugations appear (with the above exceptions) under all conditions of track, on up grades and down grades, on low rails and on high rails, on tight and loose gauges, on braking and on coasting sections, on T-rails and on grooved rails. The means which he recommends for their prevention are: (1) to construct the track so that the rail will give at least $\frac{1}{16}$ in. under a normal load; (2) the tensile strength of the rail and ties should not exceed 41 tons per square inch; (3) concrete should not be allowed to come into contact with the rails; and (4) the joints should be as light as is consistent with strength. As experience is the best—in fact, the only—guide in such cases, it is by trial that engineers will have to ascertain the value of Herr Sieber's suggestions; but that corrugations are not unknown in Nürnberg is evident from his statement that they are ground off at intervals of from one to three years, the average annual cost of removal being about £24 per mile of track.

Contributions in Relief of Rates.

At this time of year, although the results of the past 12 months' operation of municipal tramways and electricity undertakings may not yet be available, it becomes necessary for the various Committees to present estimates of their accounts for the past year, so that the Finance Committee may prepare a "budget" for the ensuing year. On such occasions efforts are not infrequently made, in view of a possible increase in the rates, to obtain considerable contributions from the prosperous undertakings owned by a municipality, and a Committee's recommendations are liable to be "amended" by the Council. In one or two recent instances where this has been done, the Chairman of the Committee in question has, and we think quite rightly, tendered his resignation in protest. Although we do not by any means approve of the principle of paying any portion of the profits of a municipal undertaking to the "common fund," any basis for a systematic contribution is perhaps to be welcomed. We may, therefore, draw attention to the fact that, at a meeting of the Electricity Committee of the Manchester Corporation last week it was decided to recommend that in future a contribution reckoned at 1 per cent. on the outstanding indebtedness of the electricity undertaking should be paid to the city fund. On this basis the amount to be contributed this year is £19,496, a considerable increase on the contribution last year. As the Tramways Committee have decided to hand over in relief of rates £75,000, a similar sum to that contributed last year, it is evident that the ratepayers will benefit considerably at the expense of the electricity consumers and tramway users.

Electricity Meter Approved by the Board of Trade.—On April 24 approval was given to the construction and pattern and means of fixing the Hookham Patent C. C. Meter, combined with Lackie's Patent Demand Indicator, provided the meter be constructed as described in specifications and drawings H. 4617 and in accordance with the pattern meter 243,093, deposited by Chamberlain & Hookham (Ltd.)

"Rational" Cooking Stove.—The "Electrical Review and Western Electrician" gives an account of a stove invented by Mr. D. Curle and known by the above name. It is constructed with a double iron casing, between the two walls of which asbestos packing is placed in order to prevent all heat radiation. The interior of the stove is divided into three compartments, the middle one of which is heated both above and below, while in the others only the lower part is heated. There are three heating resistances, each consisting of three separate units placed under perforated sheet-metal covers, which allow the heat to radiate freely within the oven. These resistances may be very easily replaced when necessary. The quantity of heat is regulated by means of switches mounted on the oven.

Cable Interruptions.	Date of Interruption.

University of Glasgow.—It is announced that Lady Kelvin has sent the Principal of this University a cheque for £500 for the foundation of a Kelvin prize. The prize is to be awarded every three years to the Doctor of Science who, during the preceding period, has offered for the degree the most meritorious thesis embodying the results of original research in physical science. A gold medal will accompany the prize.

Long Distance Wireless Telegraphy.—According to the "Railway and Engineering Review" the wireless operator in San Francisco communicated for an hour on the night of February 6 with the operator at Ghosi Shimosa, on the coast of Japan, 5,700 miles away. The messages were passed across the Pacific with one relay. It is said that the performance establishes a new record for wireless work in that quarter of the globe.

Large Central Station Battery.—According to the "Electrical Review and Western Electrician" the Minneapolis General Electric Co. has recently contracted for a large emergency battery to be installed on its system. It will consist of 260 cells of the H-67 "Exide" type and will have a capacity of 1,000 ampères at the twenty-minute rate. This will be the first battery of its kind installed by the Electric Storage Battery Co. for the Minneapolis General Electric Co.

Temporary Installations and the Coronation Decorations.—As will be seen from an advertisement elsewhere in this issue, the Corporation of London have issued a notice dealing with temporary electric light installations in connection with the Coronation decorations. In addition to regulations as to the position and size of illuminated signs, mention is made of the earthing of conduits, connecting up of wiring, &c. We notice that no bare conductors or celluloid shades and reflectors are allowed.

Electric Traction in Budapesth.—It is announced from Budapesth that the Budapesth-Czinkota-Gödöllö section of the suburban lines has recently been converted to electric traction, this being the preliminary to the conversion of all the lines in the country. The length of this section is about 20 miles long, and is double tracked throughout. Three-phase current at 10,000 volts is generated in a station at Czinkota where two 2,000 H.P. steam turbines are at present installed. The three-phase current is converted in sub-stations to direct current at 1,000 volts, while in these sub-stations batteries are also installed. The cars are fitted with 160 H.P. motors, and have been designed to run at rather over 30 miles an hour.

Automobile Line-Trucks.—The "Electric Railway Journal" gives an interesting account of a 2-ton tower automobile line truck which has recently been placed in service by the Oakland Traction Co. It has been found that in case of accidents, this type of auto-truck can be depended upon to reach the scene of trouble in one-half the time required by a horse-drawn wagon. The direct maintenance cost is small. The gasoline consumption is about ½ gallon per mile, and about a gallon of lubricating oil will serve this machine for about 1,000 miles. The dimensions of the auto-truck are as follows: length over all; width, 42 in.; height from ground to top (unloaded), 40 in.; wheelbase, 120 in. The four-cylinder vertical engine is located under the driver's seat; the cylinders are cooled by a blower. The motor control is from the throttle levers on the steering wheel. A single-lever brake is at the right of the driver's seat. The transmission is through a sliding gear of the selective type which gives four forward speeds and one reverse. The rear or driving axle is of hickory. Two brakes are provided. The gasoline tank has a capacity of 13 gallons, and the normal speed of the truck is about 18 miles an hour.

New Science Museum.—The report of the Departmental Committee which was recently appointed, with Sir Hugh Bell as chairman, to consider certain questions with regard to the Science collections at South Kensington and Jermyn-street, has been issued as a Parliamentary White Paper (Cd. 5625). The Committee find that the present exhibits are now so much crowded together that it is impossible properly to classify or utilise them. Buildings twice the size of the present would, in fact, scarcely suffice. The Committee state that this particularly applies to the Physics Section, while as regards the Mechanical Engineering Collection additional apparatus is very generally required. The Electrical Engineering Section requires to be increased to five or six times its present size. In no section is there, indeed, more urgent need of early action to secure for the Museum examples of instruments and appliances that have marked the opening of a new era in invention and industry. In the Naval Architecture and Marine Engineering Section the representation of modern types is also too limited. The Committee further suggest that it would be of advantage to establish an advisory committee to deal with all these questions, and they consider that the new buildings should include provision for an enlarged suite of workshops. A conference room, where scientific or technical societies might meet, a large lecture theatre, public demonstrations in the galleries, and the exhibition of temporary collections are also suggested.

International Competition in Practical Telegraphy.—The Italian Ministry of Posts and Telegraphs again draws the attention of British Telegraph Engineers to the forthcoming competition in practical telegraphy which will take place at Turin during the Exhibition to be opened shortly in that city. Up to the present the following countries have given notice that they are sending in teams for the contest: Germany, Austria, Argentine Republic, Belgium, Brazil, Spain, France, Greece, Hungary, Roumania, Servia, Turkey, Sweden, Switzerland, French Indo-China, New Caledonia and Madagascar; but no British team has yet been entered. It will be a pity if British telegraph engineers lose this opportunity of showing their prowess, and some effort should therefore be made to overcome the difficulties ere it is too late. The list of prizes is a long and valuable one, and includes rewards from the King of Italy, the Queen of Italy, and all the principal public administrations and cities in the kingdom. There should be little doubt that a British team could gain sufficient recompense not only to warrant its visit, but also to confer honour on the country and the telegraphic profession. All communications on the subject should be addressed to the Secretary, International Competition in Telegraphy, Ministry of Posts and Telegraphs, Rome.

Electric Train Service to the Crystal Palace.—It is announced in "The Times" that the London, Brighton & South Coast Railway will inaugurate the electric train service from Victoria Station to the Crystal Palace on May 12, the opening day of the Festival of Empire and Imperial Exhibition. It is also stated that the work of electrification is practically completed. The Company in several ways have utilised the experience gained by the working of the South London electric line from Victoria to London Bridge. For instance, the trains will be composed of six coaches instead of three or four, and the corridor, not having served the purpose of inducing people to entrain quickly, will be abolished, the extra space being devoted to increased seating accommodation. There will be first and third class compartments only. Most of the cars have already been delivered, and are at the new workshops of the Company at Norwood Junction. The route from Victoria is *viâ* Battersea Park, Clapham Junction, Balham, Streatham-hill, West Norwood, and Gipsy-hill, and this 12-mile journey will be covered in 15 minutes. The electrification of the London Bridge section from Peckham-rye, where a junction is made with the South London line, through East and North Dulwich and Tulse-hill to a junction with the line from Victoria at West Norwood, and thus to the Crystal Palace, will not be ready until after the opening day of the Festival, but there will be an accelerated service of ordinary trains *viâ* New Cross, Forest-hill and Sydenham, special through trains being timed to do the journey in 15 minutes.

"Railophone" Demonstration.—The isolation of the traveller on a railway when he is actually moving has often been the subject of comment, especially in connection with such accidents as those at Hawes Junction and Pontypridd, which might have been prevented had it been possible to commu-

Digitized by Google

nicate with the engine driver otherwise than by semaphore. To obtain such continuous communication provides a problem not easy of solution, but nevertheless it has been attacked; and on Thursday in last week Mr. Otto von Kramer gave a demonstration at Stratford-on-Avon of his instrument, known as the "Railophone," whereby continuous communication with trains is, it is claimed, rendered possible. From the point of view of the technical press the demonstration was none too satisfactory, principally owing to the fact that the inventor showed a decided reluctance, doubtless due to commercial reasons, to go into details. From the point of view of our lay contemporaries matters were apparently more satisfactory, for they were able to obtain some photographs, which duly appeared next day, of Miss Marie Corelli, who attended formally to open the installation, doing various interesting things, such as speaking on the telephone and getting out of her motor car. Mr. von Kramer in asking Miss Corelli to send the first message explained that his system was not "wireless" in the true sense of the word. Wireless methods, he said, would be affected by the rails and telegraph wires, and would give rise to difficulties from the tuning point of view. The system he employs is briefly the following. Two horizontal coils of wire are wrapped longitudinally round the frame of each railway carriage; one of these coils is of low resistance and is connected to a specially sensitive transmitter; the other of higher resistance is connected to the receiver. The source of electrical energy is 8 or 10 dry cells. We are informed that the connections are exactly the same as in an ordinary telephone installation, the above-mentioned coil taking the place of one of the ordinary transformer coils. On "land" an insulated wire is laid alongside the track and an earth return is used, this being equivalent to the other coil of the transformer. It will be seen that the apparatus is really an induction coil with the primary and secondary some distance apart. We understand that this distance has been increased up to as much as 40 ft. without speaking becoming impossible. At present the system is being tried on the Kineton and Stratford-on-Avon section of the Stratford-on-Avon and Midland Junction Railway with satisfactory results. Arrangements have also been made to establish communications between two moving trains, and even for the brakes of one or other of the trains to be applied through a sensitive relay, but no details showing how this is done were available on Thursday. We cannot help thinking that from the inventor's point of view it is a mistake to invite members of the technical press to such demonstrations before full working details of the system are ready for publication. Such reticence creates an uneasy feeling. It may be mentioned that though communication was established between a call box and a train, the latter was not moving at the time.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. C. V. Drysdale contributes an article on "The Propagation of Magnetic Waves in an Iron Bar."

A description is given of the electrical installation of the new home of the Royal Automobile Club in Pall Mall.

In our Leading Article we discuss the requirements of the Inland Revenue authorities that agreements for the sale of electricity where a minimum payment per annum is guaranteed must be impressed with an *ad valorem* stamp.

At the meeting of the Institution of Electrical Engineers last night Mr. A. M. Taylor read a Paper on "Battery Economics and Discharge Arrangements."

We give particulars of the official tests of a 3,000 kw. turbo-alternator recently installed by the Bristol Corporation Electricity Department.

At a meeting of the National Electrical Manufacturers' Association on Tuesday last Mr. L. Joseph read a Paper on "Foreign Compared with Home Industrial Finance," and an interesting discussion took place.

A new process of producing alternating-current vector diagrams experimentally was described by Messrs. A. E. Kennelly, H. G. Crane and J. W. Davis in a recent issue of the "Electrical World."

An abstract of the report for 1910 of the proceedings of the Board of Trade and the Light Railway Commissioners under the Light Railways Act appears in another column.

Islington (London) Borough Council is discussing the extension of the electricity undertaking, as well as an agreement with the Great Northern & City Railway Co. to provide a bulk supply.

At Bradford Mr. C. J. Spencer's new tramway brake has been inspected by the Tramways Committee.

Mr. Charles Bright read a Paper on "Imperial Telegraphs", at a meeting of the Royal Colonial Institute on Tuesday.

An inquiry was held on Monday and Tuesday into the application of Dublin City Council for permission to borrow £128,129 for extension of the electricity undertaking.

The joint lessees of the East London Railway have decided to convert the line to electric traction.

The Miners' Federation have requested the Executive Committee to draft an amendment to the clause of the Mines Bill relating to the use of electricity in mines.

Legal.—A Divisional Court on Tuesday dismissed the appeal of a Leeds tramcar passenger from a decision of the local stipendiary magistrate inflicting a fine of 5s. for refusing to show his ticket.

Companies' Meetings and Reports.—The report of the British Westinghouse Co. for 1910 states that the year's trading shows a credit balance to profit and loss account of £12,436. 12s. 8d. (after providing £5,642 for prior lien redemption fund and £660 towards expenses of issue of such debentures), compared with a debit balance of £7,319. 12s. in the 1909 report.

The reports of the City of Birmingham Tramways Co. and the Oldham, Ashton & Hyde Electric Tramways (Ltd.) are abstracted.

In the report of the Rio de Janeiro Tramway, Light & Power Co. particulars are given of the progress during the past year of the tramway, electric light and power and telephone undertakings of the Company.

PERSONAL NOTE.

Mr. Vincent Walker Hill, who retired as from March 31 from the position of general manager of the South-Eastern & Chatham Railway, has been elected a director of the Company, and also a member of the Managing Committee.

APPOINTMENTS VACANT.

An electrical engineer is required for iron and steel works in India See advertisement.

A switchboard attendant is wanted by the Newcastle & District Electric Lighting Co. (Ltd.) to work plant in a battery sub-station Applications to 38, Grainger-street West, Newcastle-on-Tyne. See advertisement.

Belfast Tramways & Electricity Committee require a sub-station attendant. Wages £2 per week of seven days. Applications to the city electrical engineer, Mr. T. W. Bloxam, M.I.E.E., electricity works, East Bridge-street, Belfast, by May 9. See advertisement.

A lecturer in applied mathematics is required for the Grey University College, Bloemfontein. Salary £400 per annum. Application to the High Commissioner for South Africa, 72, Victoria-street London, S.W., by May 19.

Cheltenham Local Higher Education Committee require a director for their technical schools. Salary £220, rising to £250 per annum Applications to the Clerk to the Governors by May 16.

An experienced electrician is required for a gold mine in West Africa. See advertisement.

Kilmarnock Corporation want a mains assistant engineer. Salary £2. 7s. 6d. rising to £2. 15s. per week. Applications to the Burgh Electrical Engineer by May 3.

Barnes Council require a shift engineer at their electricity works Commencing salary £120. Applications to the Engineer and Manager, Electricity Works, Mortlake, by May 4.

A mains engineer is required by an electric lighting company Commencing salary £180 per annum. See advertisement.

Digitized by Google

INSTITUTIONS AND SOCIETIES.

British Association.—The preliminary programme of this Association's meeting, which will take place at Portsmouth on August 30th and the following days, has now been issued. Sir Wm. Ramsay, F.R.S., will deliver his presidential address on the evening of the 30th, and other public discourses will be delivered on September 1st and 4th by Dr. Leonard Hill and Prof. A. C. Seward. The reception room administrative offices will be established at the Connaught Drill Hall, which is centrally situated, close to the Town Hall and meeting places. The President will have the assistance of a strong body of representatives of the administrative, ecclesiastical, naval and military interests, headed by Princess Henry of Battenberg and the Mayor of Portsmouth.

Illuminating Engineering Society.—The annual general meeting is to be held at the Royal Society of Arts on May 9th.

Electrical Trades' Benevolent Institution.—The annual dinner of the Institution was held at the Hotel Cecil on Wednesday last, the Right Hon. Lord Justice Fletcher Moulton, F.R.S., presiding. Those present included Messrs. H. Bevis, Justus Eck, E. Garcke, Hugo Hirst, J. E. Kingsbury, W. Maurice, A. J. Walter, K.C., and Major W. A. J. O'Meara, C.M.G.

The CHAIRMAN, in proposing the toast of "The Electrical Trades' Benevolent Institution," said that he was but a bad substitute for Sir William Preece, their president, though in one way at least he was a most suitable person for the position, as he was more than ordinarily ready to sing the praises of one who was his first sponsor in electrical work. One of the first occasions on which he, the speaker, consulted Sir Wm. Preece was when it had to be decided whether a particular wire was or was not a telegraph. After much experiment with a Wheatstone sounder and phonograph they were at last able to obtain vowel and consonant sounds from a telegraph, thus conclusively proving their case. He had been connected, too, with the Electric Lighting Bill of 1882, one of the greatest industrial mistakes that had ever been made, and one, too, which had stunted electrical work in this country for six precious years, during which Germany and America had shot ahead. He had watched the development of the electrical industry then from the time when it was only capable of bell-hanging and fine work, like telegraphy, to the present day when it seemed as if it were going to do the whole of the higher class work of the world. It was a trade in which there were as many officers as men. Their Society had started work on the right lines, and was being conducted on lines on which alone benevolence could be successful. The personal element wedded to self-help was present, and the management was in the hands of the trade itself. He warned them that the time had come when demands upon their accumulated funds might be made, and that it was now more than ever necessary for them to support the Institution.

Mr. H. HIRST supported the toast. He said the capital of the Institution was now £2,400, an increase of £400 over last year, while pensions to the amount of £30 had been paid out. Further, employment or temporary relief had been arranged in a large number of cases. Most of the expenses had been incurred in making the Institution more generally known in the trade. He suggested that much more might be done in this way, and that a series of prizes should be given to those members or firms who brought in the largest amounts. In early days, to belong to the electrical industry was to belong to a society like that of Masonry. There seemed to be no reason why such should not be the case at present.

Mr. A. J. WALTER, K.C., who also supported the toast, said that there were misfortunates in every industry and profession, not necessarily through any fault of their own. Rainy days might come to anybody, and sometimes it was impossible to provide adequately for them beforehand. Such a Society enabled them not only to help themselves, but to help others at the same time, and therefore wholehearted support should be forthcoming.

Mr. C. WALLIS-JONES proposed the health of the President, and Mr. FLETCHER MOULTON, in reply, announced that the subscriptions for 1911 amounted to £520, as against £320 in 1910, while £372 had been received from the funds of the Electrical Exhibition held at Olympia in 1905. Moreover, £240 had been collected in the room that evening.

Institution of Electrical Engineers.—The Students' Committee are arranging for a tour to Sweden during the third and fourth weeks in July, to visit large engineering works and hydro-electric power stations. It is proposed that the party should leave Hull on Thursday evening, July 20, and travel via Gottenburg, Trollhättan, Falkoping, Ludvika, Grangesberg, Westeras and possibly Stockholm. It is estimated that the tour will not cost more than £15. Further particulars can be obtained from Mr. D. Betts, hon. secretary of the Students' Section.

Institution of Civil Engineers.—At the annual general meeting of this Institution, held on Tuesday evening last, the result of the ballot for the election of officers was declared as follows:—*President*, Dr. W. C. Unwin, F.R.S.; *Vice-Presidents*, Messrs. R. Elliott-Cooper, A. G. Lyster, B. Hall-Blyth and J. Strain; *Members of Council*, Messrs. J. A. F. Aspinall, J. A. Brodie, W. B. Bryan, Col. R. E. B. Crompton, C.B., Messrs. Wm. Davidson, J. M. Dobson, H. F. Donaldson, C.B., E. B. Ellington, M. Fitzmaurice, C.M.G., J. P. Griffith, Dr. C. A. Harrison, Messrs. W. Hunter, G. R. Jebb, H. E. Jones, E. H. Keating, Sir Wm. Thos. Lewis, Bart., K.C.V.O., Sir Thomas Matthews, Mr. Wm. Henry Maw, Hon. C. A. Parsons, C.B., Messrs. F. E. Robertson, C.I.E., Alex. Ross, J. W. Shores, C.M.G., Hon. F. J. E. Spring, C.I.E., Sir Philip Watts, K.C.B., Mr. W. B. Worthington and Mr. A. F. Yarrow. This Council will take office on the first Tuesday in November, 1911.

The Council have made the following awards for Papers read and discussed during the session 1910-1911:—Telford Gold Medals to Mr. W. J. Wilgus and Mr. J. Walker Smith; a George Stephenson Gold Medal to Mr. Philip Dawson; Telford Premiums to Messrs. G. W. Humphreys, H. K. G. Bamber, A. E. Carey, William Dawson, and C. S. R. Palmer; and the Trevithick Premium to Mr. A. T. Blackall. The awards for Papers published in the "Proceedings" without discussion and for Students' Papers will be announced later.

EDUCATIONAL NOTICE.

Faraday House.—At a recent examination for entrance scholarships the following awards were made:—Harry Ellis Smith, Dulwich College, to Faraday scholarship of 50 guineas per annum tenable for three years. Special prizes of 25 guineas each were also awarded to Alex. Bell, Royal School, Dungannon, and W. H. Chaplin, Christ's College, London.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, April 28th (to-day).

PHYSICAL SOCIETY OF LONDON.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "High-Tension Electrostatic Wattmeters," by Prof. E. Wilson; "Previous Magnetic History as Affected by Temperature," by Prof. E. Wilson and Mr. L. C. Budd; "Note on the Behaviour of Incandescent Lime Cathodes," by Dr. R. S. Willows and Mr. T. Picton; "On the Formation of Dust Striations by an Electric Spark," by Dr. S. Marsh and Mr. W. H. Nottage.

STUDENTS' SECTION OF THE INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Meeting at Great George-street, Westminster. Lecture on "The Commercial and Technical Relations of Engineering Design and Work," by Mr. T. Frame Thomson.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "The Revolutions of Civilisation," by Prof. W. M. Flinders Petrie, F.R.S.

MONDAY, May 1st.

SOCIETY OF ENGINEERS.

7:30 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment, W.C. Paper on "The Protection of Water Supplies," by Mr. H. C. H. Shenton.

TUESDAY, May 2nd.

FARADAY SOCIETY.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment, W.C. Papers on "Hydro-Electric Plants in Norway and their Application to Electro-Chemical Industry," by Mr. A. Scott-Hansen; on "Electro-Metallurgy in the Steel Foundry," by Mr. Verdon Cutts; and on "Two Simple Forms of Gas Pressure Regulators," by Mr. E. Stansfield.

WEDNESDAY, May 3rd.

ROYAL SOCIETY OF ARTS.

8 p.m. Meeting at John-street, Adelphi, W.C. Paper on "Improvements in the Transport and Distribution of Goods in London," by Mr. A. W. Gattie.

THURSDAY, May 4th.

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Lecture on "The Optical Properties of Metallic Vapours," by Prof. R. W. Wood. Tyndall Lecture II.

FRIDAY, May 5th.

DERBY SOCIETY OF ENGINEERS.

7:30 p.m. Meeting at the Mechanics' Institute, Wardwick. Paper on "Electric Steel Furnaces," by Mr. Joh. Härden.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "New Organic Compounds of Nitrogen," by Prof. M. O. Forster, F.R.S.

BATTERY ECONOMICS AND BATTERY DISCHARGE ARRANGEMENTS.*

BY A. M. TAYLOR.

Summary.—The author first deals with the effect of rapid discharge rates on the ampere-hour capacities and terminal E.M.F.s of batteries. Methods of discharge by regulating cells alone and by boosters are discussed, and suggestions are offered for materially diminishing the cost and inefficiency of booster methods. Batteries are next considered as a standby to steam plant, and for extensions in alternating-current substations distributing direct current. The use of rectifiers for charging batteries off extra-high-tension alternating-current mains, on the premises of large consumers is also considered. An alternative proposal to batteries as a means of dealing with peak loads is finally discussed.

Rapid Discharge Rates.—The author knows of no results published in this country dealing with discharges at considerably higher values than the 1-hour rate, and though he gives some curves representing the recommendations of the Tudor Accumulator Co. in this direction, he bases his conclusions upon results actually obtained with Exide cells in New York, in which the discharge is carried to a considerably further degree than has hitherto obtained in English practice. Fig. 1 shows a curve connecting ampere-hours with hours of discharge, the values of which between the 10-hour rate and the 1-hour rate are taken from English practice, and those between the 1-hour rate and the 5-minute rate are estimated values, which, however, are very closely confirmed by the values obtained with the Exide cells given on the right-hand side of Fig. 1. In Fig. 2 are given the initial and final discharge voltages for different periods of discharge. Here, again, the English figures below the 1-hour rate are merely estimated, but it will be seen that they follow the same tendency as the actual values obtained on the Exide cells. In Fig. 3 a series of curves is given, showing the result that might be obtained on a cell of a given type and size if charged and discharged at different rates. The values of the terminal voltage on discharges below the 1-hour rate are calculated to agree with the curve given in Fig. 1. On the same sheet are shown the performances of the Tudor cells under similar conditions.

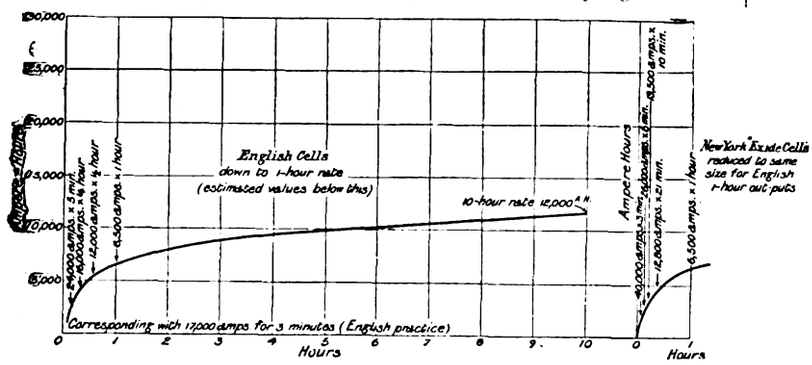

FIG. 1.

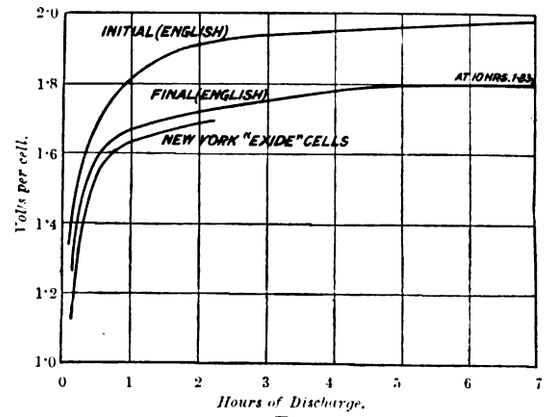

FIG. 2.

Regulating Cells.—The method of discharging large batteries by means of regulating cells has been employed on a considerable scale both in America and on the Continent, whereas in Great Britain, owing no doubt to J. S. Highfield's activities in 1901, the tendency has rather been to employ boosters for the discharge. Taking the case of a 'bus bar pressure of 510 volts, the author explains by a diagram the distribution of the charge left in the end cells of a battery where a sufficient number of regulating cells are employed to permit the battery to be discharged if necessary at the 5-minute rate. If it were never intended to use the battery at over the 1-hour rate, only 303 cells would be required (190 cells in the main battery and 113 regulating cells), and it is noted that the last 57 cells do not become properly charged unless the battery be charged at exceedingly low rates, taking a correspondingly long time, also that some of the cells are practically never discharged. This is accentuated considerably if the full number of cells (365) be installed in order to meet the extremely rapid rate of discharge (5 minutes), a larger proportion of the cells being then virtually useless except as a standby. These cells have to be fitted with regulating switch contacts, and the cost of the regulating switches becomes very considerable, besides the difficulty of maintaining cells in a healthy condition which are hardly ever called upon to give a discharge. It appears to the author that though this method of working batteries is very simple and reliable, yet it has many disadvantages, especially where rapid rates of discharge are likely to be required.

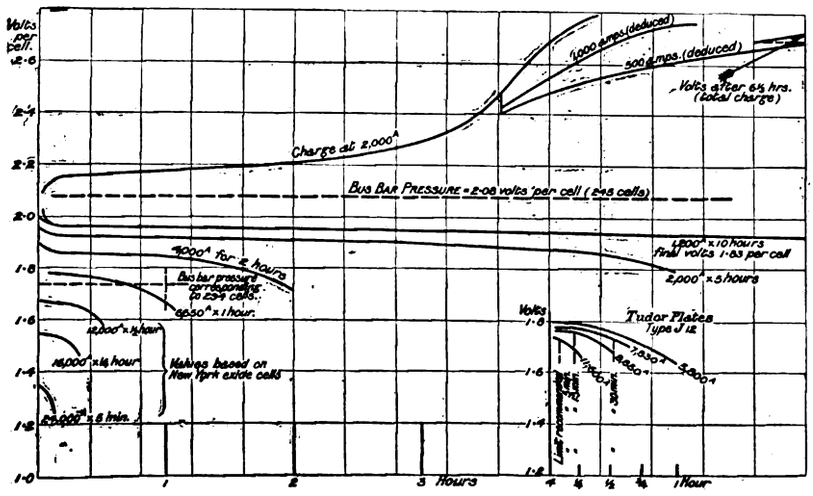

FIG. 3.

Boosters.—Up to the present time it has been very costly to obtain from boosters the necessary boost to get the discharges indicated in Fig. 1 out of the batteries. The voltage of the boosters has to be increased to such a degree that, combined with the high-current rate the resulting kilowatt capacity becomes very expensive to provide for. Virtually this has, in the author's opinion, resulted in an insufficient provision being made in boosters for discharging the battery at emergency rates, and it seems to be considered good enough either to throw the battery direct on to the 'bus bars on emergency conditions or to draw upon reserves (as, for instance, at Manchester). This, of course, means either that the batteries will never give the discharge they are capable of giving, or that, in order to obtain the discharge, the 'bus bars pressure at the station must fall tremendously. For example, in Fig. 4 the 'bus bar pressure would have to fall from 510 to 350 volts to get the discharge indicated. This is, of course, a serious matter for a central station to face. The author

...ages to show that it is practicable to put in boosters to deal with a quarter-hour discharge at a cost not exceeding what is at present spent in obtaining a 1-hour rate of discharge, and that the cost for boosters in the case of the 1-hour rate, may be reduced to less than half the sum now spent upon them, with an all-round gain in efficiency.

With a view to emphasing the extent to which the cost of the boosters may be reduced by a suitable arrangement of boosters and batteries, the author gives, in some detail, an investigation into a particular case in which it is desired to deliver an effective discharge on the bus bars of 2,530 kw. (at 510 volts) for one hour or 5,140 kw. for a quarter of an hour, or 6,370 kw. for 5 minutes. Three different methods of obtaining this result are by a battery with regulating cells, the ordinary booster arrangement of Fig. 4 and the triple series arrangement shown in Fig. 5. The waste of battery current with the ordinary booster arrangement is very considerable, and in the case of

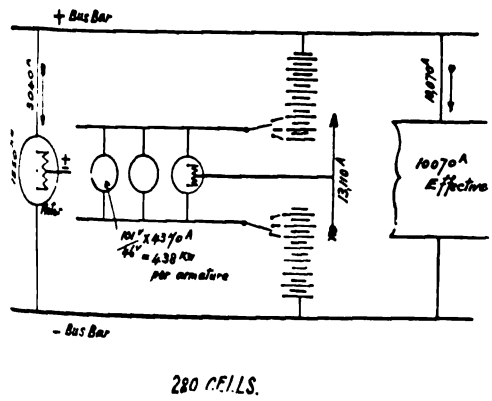

Fig. 5.

...ur rating the author shows that the output of the booster by ...s arrangement is reduced by nearly 500 kw. A summary of the conditions obtaining in the three different methods is given in ...le A, which also gives an approximate estimate of the cost of the ...ells and of the boosters.

...ig. 6 is shown a diagram of connections for obtaining the ...-series" arrangement of boosters. As shown in the right-...om corner of this diagram, a motor can be employed to ... double-wound booster armatures, each having two com-..., giving four booster armature windings, which can be ... in series or parallel; the fourth winding, however, would be ...-spare. A preferable arrangement, where cost is not a prime ...ration, would be to have two separate motors and four single-... armatures, each under its own field.

...Fig. 7 the author shows an arrangement which it appears to ... with advantage be employed in cases where the battery ... used with a regular load of known amount daily, and more ...ularly where the cells can be either charged from traction bus ..., preferably where rotary converters of the split-pole type (or ...alternating-current booster type), having a large range in their ..., are available. Where desired, existing rotary converters ... adapted for this purpose quite easily and at a low cost.

...this scheme the number of cells is so chosen that the maxi-... peak, output occurs at such a period of the discharge of the battery that practically no boost is at that time required for the latter (*see* central point of the 510-volt bus bar line of Fig. 7). For, say, one-quarter of an hour on either side of this point the boosters are worked with their armatures in parallel and are thus able to deal easily with the 6,650 amperes. During the earlier and later portion of the peak, however, the current being then much less, the booster armatures are put in series with each other. A few regulating cells, as indicated, may be employed if desired, and these could be cut out, as shown in Fig. 7, should the discharge rate require to be reduced in the early part of the discharge beyond that shown by the curve.

If traction bus bars were available, or a rotary converter could be modified to give sufficient voltage range for the charging of the cells (assisted by the battery boosters), the output of the battery boosters

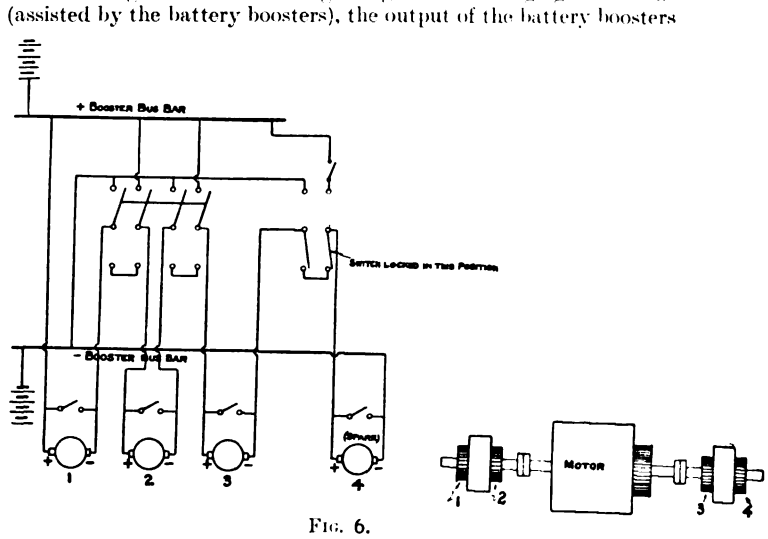

Fig. 6.

could, in the latter case, be reduced to as small a value as 66½ kw. (10 volts × 6,650 amperes). If, however, neither a suitable rotary converter nor traction bus bars were available, it would be necessary to put in boosters, if with the triple-series method, for at least 30 volts apiece, making a total booster-rating capacity on a 1-hour discharge equal to 198 kw. (30 volts × 6,650 amperes). Even this would be a distinct saving over the arrangement shown in Fig. 5, and a still greater gain over the arrangement shown in Fig. 4. In Fig. 7, however, it would be necessary to draw upon the fourth or reserve booster armature during charging (*see* Fig. 6), and it would be further necessary to arrange that the fields of all the boosters could, for short periods, be put under double the normal pressure, and also that, by speeding up the motor armature by some 30 per cent., the requisite volts on charging could be obtained.

It will be obvious that the arrangement in Fig. 7 would not be practicable if it were not feasible to make the change from series to parallel without interrupting the circuit. The author does not know of any arrangement actually on the market for performing this operation, but he sees no reason why it should not be quite practicable to combine with the double-throw switches shown in Fig. 6 certain auxiliary contacts which will perform the requisite sequence of operations.

Cells as a Standby.—The employment of accumulators as a standby against failure of the generating plant has made considerable pro-

Digitized by Google

gress in the United States during the last year or two. The cells are worked without any boosters, there being a large number of regulating cells employed.

By the courtesy of the Chloride Company, the author is able to give the following particulars, which relate to the installation of 150 cells at the Sixteenth-street sub-station of the New York Edison Company. These cells are capable of giving 10,790 amperes for 1 hour, or 21,580 amperes for 21 minutes, or 32,370 amperes for 10 minutes, or 43,160 amperes for 6 minutes. It will be noted that the 6-minute rate is four times the 1-hour rate. The battery simply floats on the 'bus bars, and the regulating switches are automatically operated in such a manner that when a sudden discharge is required they will travel along rapidly to the contact required to give the prearranged 'bus bar voltage at the prearranged discharge.

Of the total number of 150 cells the author understands that no less than 68 are regulating cells. The switches are designed to travel along from contact to contact under any current up to 40,000 amperes. The floor space required for a battery of 280 cells works out at about 0·3 sq. ft. per kilowatt for a 'bus bar pressure of, say, 460 volts. It will be readily seen that such an arrangement compares very favourably as regards floor space with boilers, engines, and alternators; and, as regards capital cost, the cost of cells alone is probably not much over £3 per kilowatt for a 6-minute rate, and

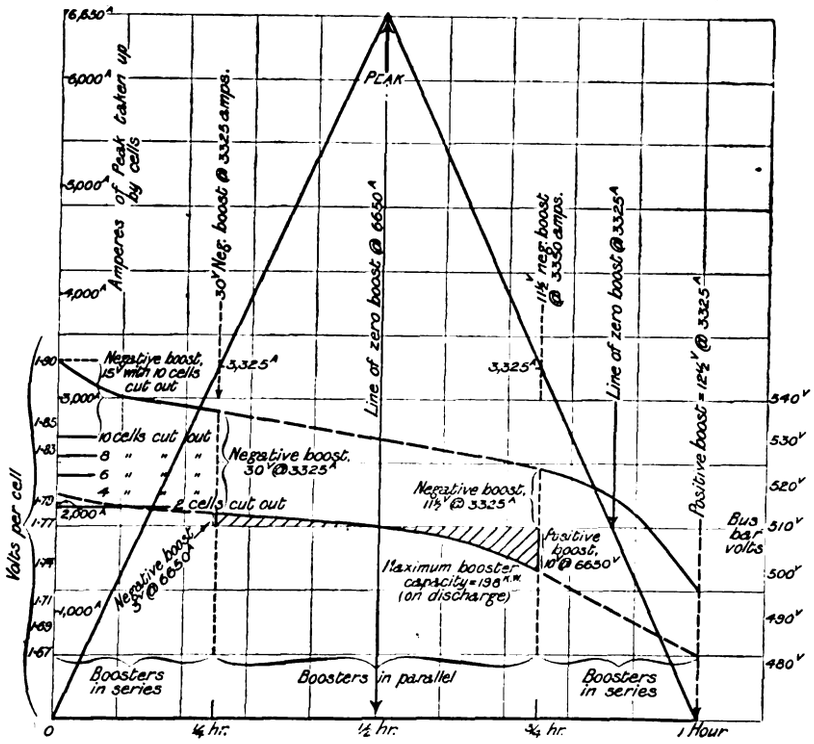

FIG. 7.—BOOST ARRANGEMENTS FOR A SPECIAL CASE.
288 cells. 'Bus bar volts = 510 (with max. number of cells).

compares very favourably indeed with any form of steam plant. Moreover, every central station engineer knows the extreme value of having standby plant which is absolutely ready to give instantaneously any discharge required from it. The battery is normally arranged to float on the 'bus bars and receive a slight charge, so that at the commencement of any emergency demand the battery is giving its full voltage, and the number of cells to be installed is thus reduced somewhat below that given in Table A.

The extent to which this method of employing batteries has obtained favour in the United States will be understood when it is stated that in the year between June, 1909, and June, 1910, batteries have been installed in New York, Chicago, Brooklyn, Boston and Washington, aggregating some 49,000 kw. at the 6-minute rate. The author, however, thinks that, valuable as this special class of battery may be as a stand-by, the savings to be introduced by working the battery in a regular way as a substitute for the use of steam plant, where the load is of a peaky nature, are so great that it will not be found advisable to put in batteries exclusively for the one class of work.

The author suggests that where batteries are put in on a large scale for lighting purposes, it will generally be found preferable to put in those batteries which deal with what may be called "time" peak (as distinct from "instantaneous" peaks) arranged to be operated by hand-regulated boosters; but, since the voltage of a battery alters very considerably with its rate of discharge, it would also seem

5	20	3·89	0·150	7,384	3·89	0·220	8,250

desirable to have a smaller battery, which might be of the nature of a buffer battery, to take up the "instantaneous" peaks by means of an automatic booster, and so keep the 'bus bar pressure constant, while the main battery would be regulated by hand in such a manner as to enable boilers and engines to be shut down to the maximum possible extent.

Economy of Accumulator Working.—The case chosen is one involving the delivery of an additional peak load of 1,450 kw. on the direct-current 'bus bars in a sub-station at a distance of 1 mile from the main generating station, representing a load at the generating station of, say, 1,540 kw., the transmission being by high-tension alternating current and rotary converters. A number of tables are given showing the capital cost and the annual cost of delivering this additional amount of power for one, two and five hours daily by means of extra steam plant, extra gas plant and by accumulators. Table B herewith summarises the above tables.

It will be seen that on a 1-hour basis and with coal at 8s. per ton the total annual cost with the batteries is only £2,752 as against £5,576 when delivering the power direct to the 'bus bars without cells by means of rotary converters. The higher the fixed charges and the lower the running cost of the generating plant, the better does the battery show up as a substitute for it. It would seem, therefore, that where the average duration of the load supplied by the accumulators is from one to two hours and coal is moderately cheap, there is undoubtedly a good case for accumulators. Even, however, where coal is dear there is generally a sufficient saving in standby losses to make the value of the coal so saved fully equal to that lost in the inefficiency of the battery. This is exemplified in the case of Manchester, where the coal consumed per unit delivered to 'bus bars at Dickinson street, for a particular period of the year, is stated to have been reduced by 25 per cent., this taking account of the losses in the accumulators and boosters.

Accumulators with Alternating Current.—The introduction of the split-pole rotary converter, as developed in the United States, has given an incentive to the use of batteries on alternating-current systems as equalisers of the load. No doubt the employment of accumulators on alternating-current systems would be greatly extended if some less expensive and more flexible means could be introduced for charging and discharging them than that employing rotary converters. The author has devised a rectifier which he anticipates will permit of momentary overloads being passed through it many times larger (proportionately) than those which would cause the commutator of a rotary converter to flash over, and which should also be capable of dealing with large currents and of commutating direct currents into alternating currents.

The author thinks, however, that if it can be shown that, even in pure alternating-current distribution, the employment of battery substations will not only reduce the amount of generating plant as well as the aggregate section of the extra-high-tension feeders by some 20 to 30 per cent., but will also reduce the amount of wattless current to an insignificant amount, engineers will think twice before they dismiss the double advantage on the sole objection that to introduce substations with rotating machinery requiring skilled attention, in place of feeders, would be a retrograde step. As regards reliability of supply, it certainly would not be this, even if no pecuniary saving were obtained.

Digitized by Google

The cost of entirely new sub-stations, rotaries, &c., will not be materially different from the figures given in the tables referred to above (except that rotaries and switchgear have to be added); and, if a good case has been made out for putting in accumulator plant in existing rotary converter sub-stations to save the first 20 to 30 per cent. of the generating station plant and feeders above alluded to, it should be pretty clear that the additional conversion losses in re-transforming back to alternating current are more than compensated by the additional 10 to 20 per cent. of generating plant and feeders saved on account of improved power factor.

The author states here his proposals for improving the power factor in a pure (or mixed) alternating-current system. Referring to Fig. 8, the rotary converter or motor-generator (A) and its battery (C) are used for taking up the peaks of the load in a manner well understood. The second rotary converter, motor-converter or motor-generator (B) is a synchronous machine and is over-excited in such a manner that it runs as motor, fed from the alternating-current line, and draws a leading wattless current therefrom sufficient in value to compensate for the lagging wattless currents taken by the consumers' motors. The special feature of the author's proposal is that the rotary converter (B) is enabled to find a useful load for itself by charging the battery (D), and thus a given kilovolt-ampere motor load can be dealt with with a much smaller expenditure in synchronous machines than would otherwise be the case. When the evening peak load comes on, the charge in the battery (D) is available for assisting the rotary (A) to deal with the load; and the motor-generator B may be either used to perform phase-changing by itself or, if not needed for that, is available to assist the motor-generator A in dealing with the peak.

Alternative to Batteries.—An abstract has recently appeared in the "Electrical World" of a Paper read before the American Street and Urban Engineering Association by Mr. H. G. Stott, in which the use

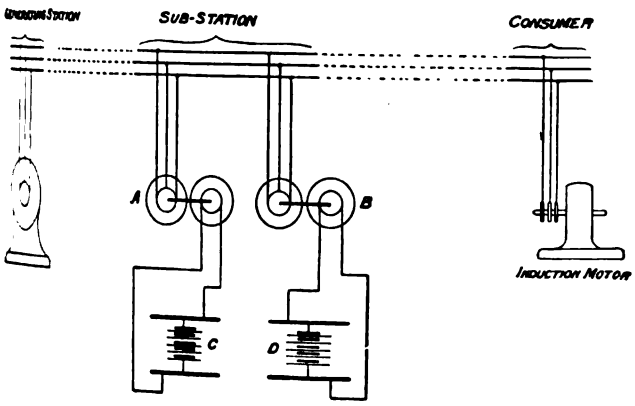

FIG. 8.

of batteries for peak loads is unfavourably compared with a scheme put forward for providing the extra power for extensions (in stations using reciprocating engines) by adding exhaust turbines to carry the load, by adding grate surface to the existing boilers, and by forcing the boilers during the time of peak load. The disadvantage which Mr. Stott's proposal labours is that the stand-by coal required to keep the boilers going through the night will still be required much as before. Moreover, the steam units cannot be so economically loaded up at all times of the day and night as by the use of batteries. Another point apparently overlooked is that the battery introduces the extra capacity at the wrong point; it should be essentially introduced at the sub-station.

The author of the present Paper deals in detail with Mr. Stott's proposals and believes that for peaks of short duration, say, up to two hours, batteries will be found decidedly the cheaper, and, moreover, little additional staff will be required than with the turbo-exciters. The question of power factor also has to be considered, and is a further inducement towards the use of batteries.

Conclusions.—The fact that batteries can now be constructed, and are being made, which will give outputs up to 40,000 amperes, shows that the Tudor plate type of accumulator has passed the experimental stage from the point of view of reliability, and central station engineers need no longer be afraid that if they put in a battery they may have to scrap it at the end of two or three years. Battery makers of repute are now to be found who will undertake the maintenance of cells for periods of 10 to 20 years. Even if this were not so, the new Tudor cell appears to have wonderful characteristics, as may be seen from tests recently published in THE ELECTRICIAN. The author is, unfortunately, unable to give an idea of its cost; but, as things are at present, it would seem to be quite safe to instal large batteries of the lead-plate type, and even if, in a few years' time, the long-expected ideal battery should make its appearance, no particular loss would be involved, provided a life of some seven years had already been obtained out of the lead-plate battery.

Three appendixes are attached to the Paper. The first gives a list of Tudor batteries having an output of over 500 kw. supplied by the German Tudor Co.; the second, a few particulars of some batteries installed in large U.S.A. central stations; and the third deals further with Mr. Stott's proposals.

A NEW AND DIRECT PROCESS OF PRODUCING ALTERNATING-CURRENT VECTOR DIAGRAMS EXPERIMENTALLY.*

BY A. E. KENNELLY, H. G. CRANE AND J. W. DAVIS.

The properties of the rotating magnetic field and their relation to two component quarter-phase magnetic fluxes are well understood. It seemed that analogous properties should be developed by a rotating electric field. Such a field should be capable of being produced either in a dielectric medium by two quarter-phase displacement currents or in a conducting medium by two quarter-phase conduction currents. Attempts to produce the latter, or voltaic, form of rotating electric field in a reliable manner were commenced in the electric engineering laboratories at Harvard University in April, 1910, using a thin sheet of acidulated water in a flat insulating tray as the conducting medium and a telephone receiver as the detecting instrument. Recently, however, very successful results have been produced with thin metallic sheets as the conducting media and a vibration galvanometer as the detecting instrument.

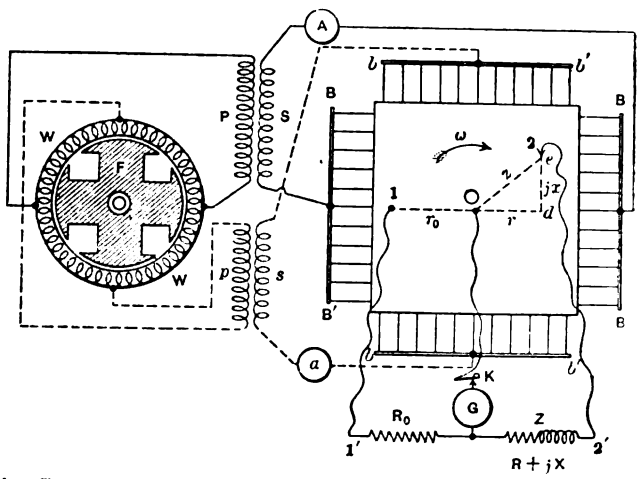

FIG 1.—GENERAL CONNECTIONS OF METALLIC SHEET, INDICATING THE PRODUCTION OF A VECTOR DIAGRAM OF IMPEDANCE.

The metallic sheets used have been composed at different times of tinned iron and of zinc. The results have been essentially the same with both substances, and only the zinc sheet will be here considered. The sheet was of commercial zinc 81·5 cm. square and 0·46 mm. thick. Its surface was marked off into centimetre squares—*i.e.*, into a system of rectangular co-ordinates. Connections were made with the edges of this plate through a fringe of high-resistivity wires, some high-resistivity fringing for the sheet being necessary in order to keep the electric current flow lines parallel to the edges. As shown in Fig. 1, 11 wires, each 29·5 cm. long, were soldered to each edge of the sheet at uniform intervals of 7 cm. The resistance of each wire was 0·836 ohm. The joint resistance of all the 11 wires in one fringe was thus 0·076 ohm. The entire flat arrangement of sheet and fringes was mounted on a wooden frame about 150 cm. square. This frame was supported conveniently in a vertical plane against a wall.

In order to produce a rotating electric field in the sheet two single-phase currents of equal strength, differing 90 deg. in time-phase, were supplied to it, with one component single-phase current along each axis. The general connections are illustrated in Fig. 2. The current density at any point in the sheet thus becomes a plane vector, rotating with the angular velocity of the alternating current. The frequency used was between 50 cycles and 60 cycles per second. Since the current-density rotated, the electric intensity, or volts per centimetre, at any point in the sheet, due to IR drop, was also a rotating vector. If appreciable harmonics existed in the currents supplied to the sheet, the resultant rotation would be non-uniform in radius vector as well as in angular velocity. The actual complex rotation

* Abstract of an article in the "Electrical World."

Digitized by Google

would, however, in all cases be reducible to a pure uniform rotation of fundamental frequency, together with superposed pure uniform rotations of harmonic frequencies at harmonically increased angular speeds.

The instrument used to detect the rotating field was a Campbell bifilar vibration galvanometer, constructed by Mr. R. W. Paul, of London. A flexible conductor was soldered to the centre of the sheet at O, and led to a contact key K and the vibration galvanometer G. Another flexible conductor was permanently soldered to the point 1 on the reference axis, at the distance ·35 cm. from O. This wire led to a substantially non-inductive standard rheostat, R_0. For convenience in the measurement of low impedances, this rheostat was plugged for 3·5 ohms; for moderate impedances 35 ohms and for still higher impedances 350 ohms. In this way each centimetre of distance along either axis of the plate represented either 0·1 ohm, 1 ohm or 10 ohms respectively.

With the connections as shown and the impedance Z to be measured there is found to be only one point on the plate at which a roaming wire from Z can touch and show no current in the vibration galvanometer with the latter in tune and the key K closed. If the measured impedance Z happens to be reactanceless, the roaming contact must be made along the line 1O*d* of the reference axis, and the length O*d* of this line then measures to scale the resistance of Z. But with magnetic reactance in the coil, as shown, the roaming contact must be moved to a certain point *e* off the reference axis, and such that O*d* reads, to centimetre scale, the effective resistance of the coil Z, *de* reads to the same scale its effective reactance, and O*e* to the same scale its impedance, all to fundamental frequency. This may be called the simple harmonic impedance of the coil Z. If the coil has no iron core, there will usually be no appreciable difference between the ordinary complex harmonic impedance and this simple harmonic impedance. With an iron core present hysteresis tends to establish some difference between these quantities.

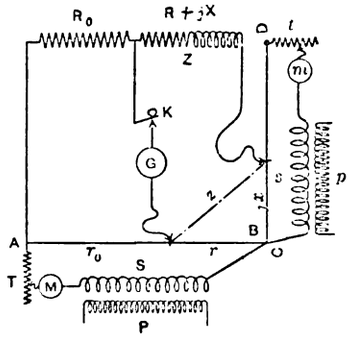

FIG. 2.—TWO-DIMENSIONAL POTENTIOMETER.

In all cases, whatever be the resistance represented by 1 cm. on the sheet, the relation is $Z/R_0 = z/r_0$.

If the direction of rotation of the electric field is as shown by the arrow in Fig. 1, then a magnetic impedance will lie on the $+j$ side of the reference axis, as shown, and a condenser impedance on the $-j$ side. But if the direction of field rotation be reversed, by reversing either of the main switches, the sign of the j-component, or reactive component, of the impedance will be reversed upon the sheet.

The action in Fig. 1 may be explained as follows: With the electric intensity rotating clockwise, as shown by the arrow at ω, the P.D. along the line O*e* on the sheet will be ahead in phase of the P.D. along O*d*, the reference axis. The current in R_0 is in time-phase with the P.D. 1O, or along r_0, if there is no reactance in the path $1'R_0$. The current in Z is delayed in time-phase by the reactance of the coil. The P.D. impressed on Z must, therefore, be advanced in time-phase by the angle *e*O*d* in order that the current in Z shall be in time-phase with the current in R_0. The identity of these two currents, both as to magnitude and time-phase, is disclosed by the absence of current in the galvanometer G when the key K is closed.

A difficulty which soon presented itself in these experiments produced discrepancies that evaded analysis for some time. Unless care be taken to remove all stray magnetic flux from the galvanometer circuit, the voltage induced by a stray field may mask or dominate the P.D. rotating in the sheet. It was found necessary to bind the wires 11′, O, K, 22′ tightly into a queue from the centre of the plate, to use twisted pairs for the supply wires, and to take other like precautions. An ideal arrangement, with this difficulty in view, would be to use a return current sheet side by side with and of the same dimensions as the working sheet, the two being separated only by a thin layer of insulating cloth so that the two exciting circuits could be kept almost completely non-magnetic. No such compensating return sheet was used, but even after all precautions were taken it was found desirable to take two readings at each measurement, the current being reversed in both supply circuits at each alternate reading.

A number of interesting alternating-current phenomena of impedance can be demonstrated with the revolving electric sheet of current and potential. Thus, if the impedance Z (Fig. 1) consists of the primary winding of a small induction coil, the effect of short-circuiting the secondary winding is to increase the resistance component O*d* of the resulting impedance and to diminish the reactance component *de*. Again, the increase of reactance in a reactive coil with increase of frequency is readily shown.

As may be easily demonstrated, the mesaurement is made with greater sensitiveness and precision as the standard R_0 and the unknown Z are reduced in impedance. The best results to begin with are obtained with a standard resistance R_0 of only a few ohms, a measured impedance of Z about the same magnitude, and with the galvanometer carefully tuned.

There are various other ways of obtaining measurements and vector diagrams with the rotating-current sheet. Thus, the test circuit may be connected to two points along the reference axis, and a balance obtained by a roaming contact leading to the galvanometer. Some beautiful geometrical relations and figures present themselves in the different tests and connections.

The vector diagrams obtained from the rotating current sheet, particularly with the arrangement shown in Fig. 1, are concrete experimental realities, very different from the geometrical abstractions which vector diagrams have hitherto appeared to consist of in alternating-current literature, and any observer who with such an apparatus, actually experiences a vector diagram will probably carry away with him a lasting and a different impression of such a diagram from that set up in the mind merely from the perusal of text-books. The rotating-current sheet is an ideal source of instruction in this respect.

Whether the rotating-current sheet can be made into an accurate piece of measuring apparatus, or two-dimensional potentiometer, is, however, an open question. It is swift to work with in measuring impedances, but in the form above described its precision is limited. Large sheets supplied with powerful currents using anti-induction precautionary devices may improve the precision, but since the currents are distributed broadcast over the whole sheet surface, the degree of precision per ampere of supply current must necessarily be small. Moreover, it may be difficult to secure a sufficient degree of mechanical uniformity in the thickness of large-surface metallic sheets, although corrections could be found, with sufficient care in the use of continuous currents and with a direct-current potentiometer.

A more promising method of obtaining a two-dimensional or vector diagram alternating-current potentiometer, which has recently been tried by the authors, is shown in Fig. 2. The quarter-phase currents are supplied, of adjusted equal strength, to the two slide wires AB and CD, which are connected together at B. Using the standard reactanceless resistance R_0 in series with the impedance Z to be measured, balance at the two sliding contacts can be secured with no current in the vibration galvanometer, when $R_0/R = r_0/r = jX/jx$.

The supply currents required in the slide wires are now comparatively small, and the precision of the apparatus as a measuring device is much greater. The balance adjustment is thrown on two sliders, which must be moved successively to a joint balance, whereas in the case of the rotating-current sheet there is only one roaming contact point, although the direction of motion for securing balance at any instant is uncertain, being of two degrees of freedom. In the non-rotating current two-dimensional potentiometer of Fig. 2 it seems possible to secure the required two-phase voltages from a single-phase source by using a small transformer with no iron core. Experiments are being made in this direction.

When the current is rotating at full speed in the sheet it is not an easy matter to reveal its presence except with the aid of a vibration galvanometer, but if the quarter-phase alternator supplying the currents is slowed down to a frequency of only one or two cycles per second, a small compass needle supported over the sheet can be brought into synchronous rotation with the current and so make the rotation evident to the eye.

Tram Car Indicator.—A new method of facilitating the tramway traffic on the Embankment has just been introduced in the shelter at Blackfriars Bridge. A megaphone is suspended from the roof of the shelter, and as each car approaches its destination is announced as well as the number of vacant places that are available both inside and out. Behind the megaphone instrument is a loud speaking telephone of the Graham type through which the information is given by an official stationed on a refuge opposite H.M.S. "Buzzard."

ELECTRICAL EQUIPMENT OF THE NEW BUILDING OF THE ROYAL AUTOMOBILE CLUB, PALL MALL, LONDON.

In one way, at any rate, the Royal Automobile Club may be said to be unique among clubs. Not only does it, as do all other clubs, provide food, rest and entertainment for its members, but it also concerns itself with the advance of the science of automobilism, and by means of standing committees helps to obtain information which shall be of general use. For these reasons it requires more extensive accommodation than would an ordinary Club. It must provide offices for a more than usually large secretarial staff as well as suitable meeting places for the members of its various committees. With all these various operations, it was soon found that the Club's premises in Piccadilly were too restricted and the inevitable leakage into adjoining buildings occurred. To avoid the inconveniencies thus caused it was decided to obtain a site on which a new building, capable of containing everything under one roof, could be erected. Finally, the land in Pall Mall on which part of the old War Office used to stand was obtained on lease from the Office of Works. As regards position, nothing could be more central, while the building that has been erected is quite worthy of the district.

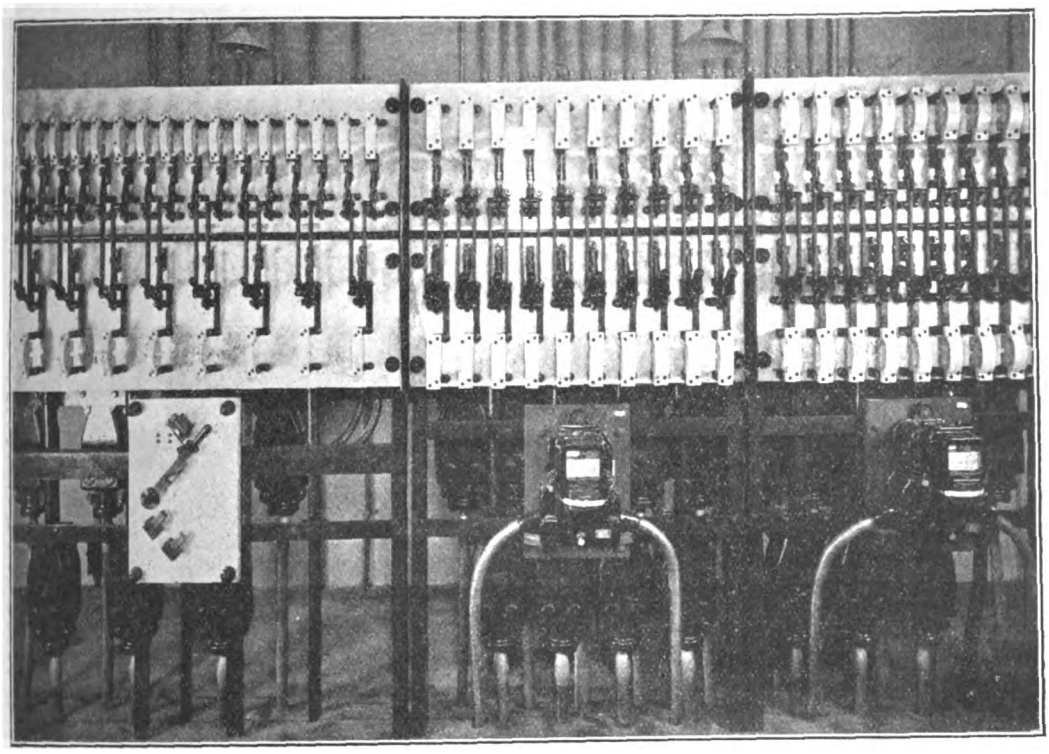

FIG. 1.—VIEW OF ONE OF THE MAIN SWITCHBOARDS.

The site has a frontage of 225 ft. to Pall Mall, with an average depth of 148 ft. The rooms at the back look directly out over St. James' Park. Great attention has been paid to the interior architectural effects and the results in general have been very successful. From the main entrance hall, a reception room and strangers' room open out to the right and left respectively. A flight of stairs leads up from the hall to a two-storey elliptical vestibule, beyond which is the Great Gallery,

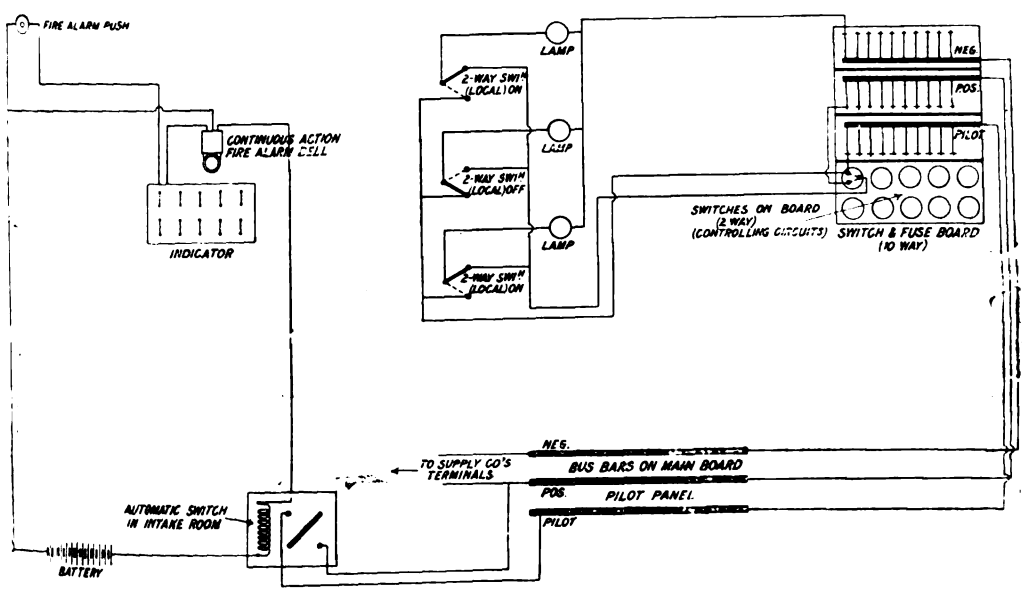

FIG. 2.—DIAGRAM SHOWING CONNECTIONS OF THE FIRE ALARM SYSTEM.

Digitized by Google

also built in two storeys, with a balcony and a platform. To the right of the vestibule is the club room, and to the left a dining room and restaurant. On the first floor is the members' dining room which is decorated in the William Chambers style, a billard room with three tables, card room, committee room and library. The chief feature of the second floor is a fine room in the Georgian style which opens on to the terrace formed by the roof of the Great Gallery. On this floor there are also a few bedrooms. The third and fourth floors are fully occupied by bedrooms, while on the fifth floor are the servants' quarters and a photographic studio. The lower ground floor contains the kitchen and cloak rooms. In the basement are a swimming bath, Turkish bath, fencing room, shooting range, racquets courts and dressing rooms.

The building is made up of nearly 2,000 tons of structural steel work which forms the main frame of the building, the columns being supported on separate foundations.

Messrs. Mewes and Davis, and E. Keynes Purchase were the joint architects; the consulting engineer for the electrical work

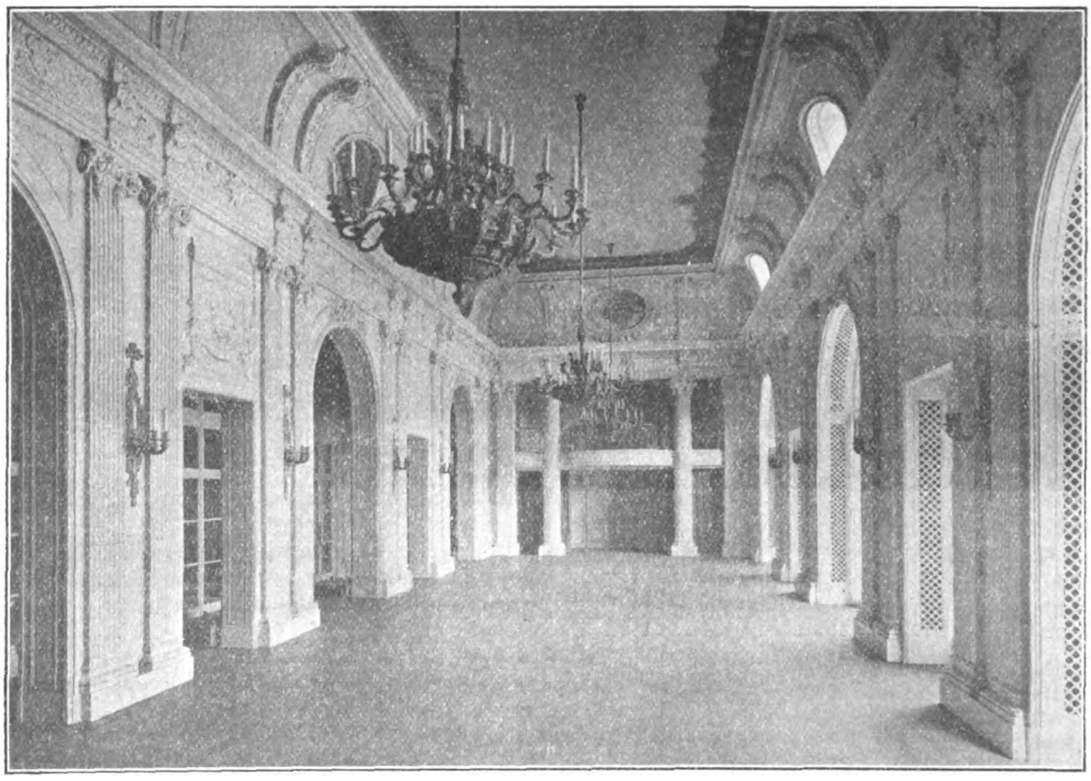

Fig. 3.—The Great Hall from the Platform.

was Mr. E. Wingfield Bowles, and the general contractors were the Building Construction Co. The entire electric light, power, bell and fire alarm installations as well as the conduit for the G.P.O. telephones, was carried out by the well-known firm of Higgins & Griffiths, on the most up-to-date lines.

The actual building was finished in 15 months at a cost of £240,000. As regards the electrical equipment, great care has been in the first place taken to prevent all the lights being extinguished at one and the same time. For this reason the lighting and power is supplied from two separate mains of the St. James' and Pall Mall Electric Light Co. The supply company's mains enter the building at two separate places, each cable being fed from an entirely distinct source of supply; in one case direct from Carnaby-street, and in the other through a sub-station from the Central Electric Supply Co.'s station at St. John's Wood. The supply is at a pressure of 110 volts direct current for lighting and 220 volts for power.

The supply mains come into a special chamber where switches and fuses are fitted, and thence pass to the intake chambers. One of these is provided for each of the two supplies. They consist of a good-sized fireproof room (securely locked) and contain the double-pole switches and fuses controlling the sub-main circuits. These are fixed on marble boards fastened to iron framing to which are also fitted integrating meters for determining the energy consumption in various parts of the building. A view of one of these boards is shown in Fig. 1.

The general arrangement of the supply is as follows:—The building is divided approximately into two halves, each half having an entirely separate intake chamber. Each room is lighted from both mains so that should one of the supply company's mains break down, the whole of the building would still be lighted. Further, all the corridors and halls are lighted from a special fire alarm circuit, details of which are given below. The mains from the intake chamber to the main boards, and from the main boards to the sub-boards are paper insulated lead-covered and armoured, and are run up special shafts along adjacent staircases. These shafts are easily accessible should it be necessary to inspect the cables.

At each intake point the St. James' Company come in with a three-wire service for lighting, and a two-wire service for power. The arrangement employed for controlling the pilot lighting is exceedingly ingenious. The mains on one pole are split and pass in parallel through a two-way switch. One side of this switch supplies the various lamps through sub-distribution boards and special local switches in the ordinary way, and the other supplies the lamps direct through sub-distribution boards and the other portion of the local switches. The pilot circuits on one side are further controlled by a single-pole switch, which, in its normal position, is held off by a catch. When the fire alarm is sounded by means of pushes in any part of the building, the coil on this switch is energised and the catch pulled off. The switch then falls by gravity and switches on the pilot lights throughout the staircases, corridors, &c., of the building. There are in all eight pilot circuits controlled as explained above by a 50-ampere triple-pole switch.

Digitized by Google

and fuses. Fig. 2 gives a diagram of the cut-in switch arrangement.

There are altogether 52 general lighting circuits controlled from these boards, some of which are fed from the Carnaby-street mains and some from the sub-station. All these circuits have a capacity of 100 amperes; 12 of them supply the basement and are metered separately, being charged on a special tariff. There are also 12 power circuits supplied at 220 volts for working the lifts and fans, and two 110-volt circuits, one for supplying the cinematograph in the lecture theatre and the other supplying apparatus in the photograph room.

From the sub-boards the wires are run in steel screwed conduit placed under the floors. Where the conduit enters the draw-in boxes it is fitted with brass bushes. The draw-in boxes are easily accessible through traps in the floor and are provided with flush lids. All the conduit has been laid down to be electrically continuous throughout. The conduit is earthed at each intake room and distribution board by a 7/16 cable connected to the nearest water pipe. It was tested for continuity by ringing an electric bell through it. All the conduit is of ample size for the wires it carries, and to ensure that repairs could easily be made if necessary every wire was drawn into the conduit.

The distribution boards are contained in cast-iron cases painted with uralite, and are sunk in the walls. The fuses are carried on marble panels, the two poles being carefully insulated. Tubular fuses of 10 ampere capacity are used on the lighting boards. Front connections are employed throughout, and great care has been taken to keep the circuits fed from different sources of supply entirely separate. The various runs of conduit are placed quite apart under the floor, so that no switch or fitting on one circuit is within 6 ft. of any switch or fitting on the other circuit. The distribution boards for the general lighting and of the pilot lighting are placed so far apart that no man working on one can, even intentionally, touch the other. Further, they are divided into two halves, so that while the fuses can only be replaced by the electrician, the switches can be turned on or off by the ordinary attendants.

To make further separation the two sets of circuits fed from the two supplies are wired with different coloured wires, red and black being used on one circuit, and blue and yellow covered wires on the other.

The switches throughout the building are of the flush type, with the exception of those on the service and fifth floors; Lundberg plugs are used throughout, and where heating circuits are employed, a device is employed to prevent the heating plug being inserted in the lighting socket and vice versa.

A complete bell installation is provided on each floor, and is fed from batteries in the ordinary way.

In the main club rooms special attention has been paid to the lighting. This will be obvious by referring to Fig. 3, which shows a view of the Great Gallery. This chamber is decorated throughout in the style of Louis XV., and for lighting both candelabra and brackets are used, the place of the candles being, of course, taken by electric candle lamps. The same idea is followed out in the other main rooms with excellent results. In the swimming bath, for instance, which is decorated in an early Italian or Roman style, massive Greek bronze pendants of triangular shape with a lamp at each corner are used, the effect being very striking, while standards, also of Greek pattern, are placed near the edge of the bath. For lighting the bath itself, that is the water, metal filament lamps sunk in the cornice are used, the result of which arrangement can be seen in Fig. 4. The racquets courts too presented an interesting problem from the lighting point of view. It is, of course, necessary, in order that play be possible, that the ball shall cast no shadow. This condition was at last obtained after some trouble by using lamps suspended from the ceiling and placed in a reflecting trough inverted so that all the light is thrown downward. The most suitable height of these troughs was determined by experiment, and it was only after several heights had been tried that the one at last reached was chosen.

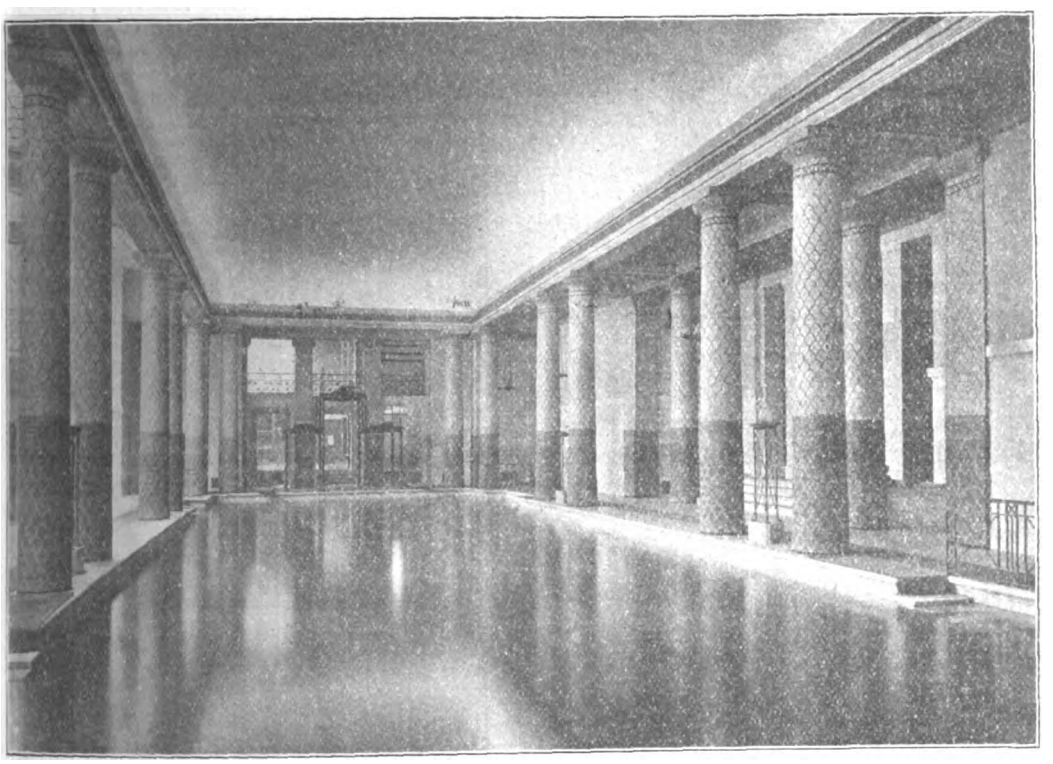

FIG. 4.—THE SWIMMING BATH.
Photographed by artificial light. The effect of the concealed lighting near the ceiling is noticeable.

In conclusion, we have to express our indebtedness to Mr. J. W. Orde, secretary of the Royal Automobile Club, for allowing our representative to inspect this most interesting building.

LOSSES ON HIGH-TENSION LINES.*

BY G. FACCIOLI.

This Paper gives the results of tests on corona losses taken on the lines of the Central Colorado Power Co. The three conductors of the three-phase line are situated in a horizontal plane, with a distance of 124 in. between centres of adjacent conductors. Each conductor between the power house at Shoshone and Denver consists of a hemp centre six-strand copper cable No. 0 B. & S. gauge, with the exception of a section between Leadville and Dillon, where the conductors are of smaller size. From Denver to the power plant at Boulder three six-strand copper cables, No. 1 B. & S., are used (*see* Fig. 1). The insulators are all of the suspension type, and have four insulating discs each. The altitude and the climatic conditions of the country

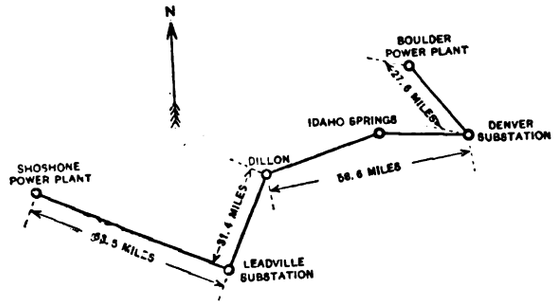

FIG. 1.

traversed by the transmission line are unusual. The line crosses the continental divide at three points, one between Shoshone and Leadville at an altitude of 12,000 ft., another between Leadville and Dillon at 12,500 ft., and the third between Dillon and Denver (Argentine Pass) at 13,700 ft. These exceptional conditions magnify the importance of the problem of line losses, as it is well known that the atmospheric losses increase with the altitude.

The generating system at Shoshone consisted of a 5,000 kw. 4,000-volt 60-cycle three-phase alternator, connected to the low-tension side of three 3,333 kw. transformers, whose ratio of transformation was 4,200 to 100,000 volts. The generator windings were Y-connected, the three transformers being delta-connected on both

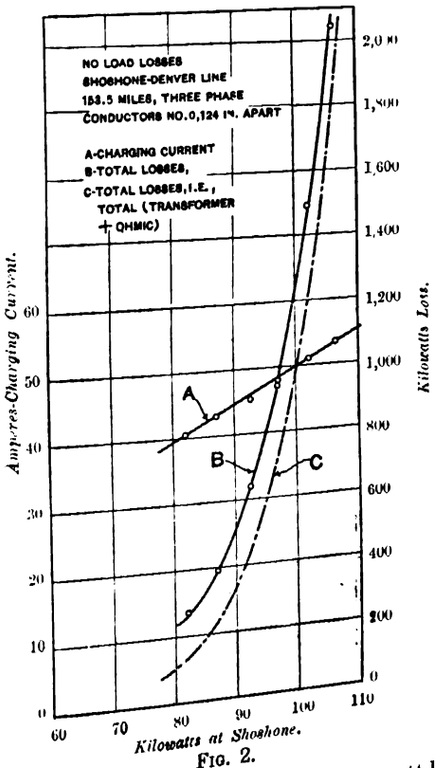

FIG. 2.

primary and secondary sides. Fig. 2 gives the kilowatt losses of this three-phase line (153·5 miles long). The voltage was varied by regulating the excitation of the alternator, and the measurements were taken on the low-tension side of the step-up transformers as follows: First, the transformers alone were connected to the generator, and the transformer losses recorded at a certain voltage; second, the line was connected to the high-tension terminals of the transformers and the loss measured at the same low-tension voltage. The difference between the two readings gave the total line losses —*i.e.*, the sum of ohmic, corona and insulator losses.

In Fig. 2, curve A shows the charging current of the line, and curve B gives the total losses measured at different voltages, that is to say, the line losses plus the transformer losses. Curve C gives the corona and insulator losses—*i.e.*, the losses remaining after the ohmic and the transformer losses have been subtracted from the total measured losses.

At 100 kv., which is about the operating voltage of the system, the transformer losses are 52 kw. and the corona and insulator losses 1,003 kw. Thus the operation of this system at 100 kv. would appear impracticable. However, when the system is loaded and in normal operation the line losses fall to small values, well within the limits of economical operation. The explanation of this phenomenon is obvious.

When the line is unloaded the voltage increases along the line, until at the far end of the line, at Denver, it is more than 10 per cent. higher than at Shoshone. With two 2,500 kw. transformers connected at Denver in open delta it was found that with 90 kv. at Shoshone the voltage at Denver was 100 kv. Hence the majority of the 1,000 kw. measured when 100 kv. were held at Shoshone was concentrated at the far end of the line, where the voltage was above 110 kv.

The above tests cannot be used to determine the critical voltage or the law which connects losses to kilovolts, because the voltage at the far end of the line is higher than the voltage at the power house, and because of the different altitudes through which the transmission line runs. For this reason some experiments were conducted on the Denver-Boulder section of the system.

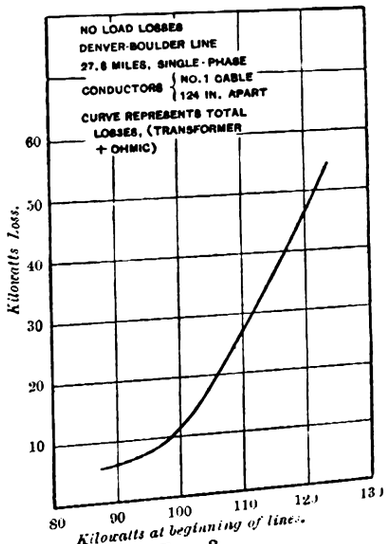

FIG. 3.

The distance between Denver and Boulder is 27·6 miles, and the line runs at an average altitude of 5,300 ft. The conditions of the majority of the tests were as follows: The main line from Shoshone to Denver was energised under normal conditions. The voltage at Denver was stepped down from 100,000 volts to 13,200 volts, and power was delivered at this voltage to the 13,200-volt 'bus bars at Denver. The low-tension winding of a 2,500 kw. single-phase step-up transformer was connected to these 'bus bars, and the high-tension winding energised two of the conductors of the three-phase line from Denver to Boulder. Different voltages were obtained by using different ratios of transformation or different combinations of step-down and step-up transformers.

The measurements were taken for a period of two weeks during which the barometric pressure varied from a minimum of 24·1 in. to a maximum of 24·7 in.; the temperature varied from 49°F. to 74°F. and the relative humidity from 21 to 35 per cent. with an average of 29 per cent. These values were measured at Denver. It was found that readings taken on different days were not affected by humidity for which, therefore, no correction was made. Also no correction was made for the slight difference in barometric pressure and temperature. The results regarding humidity obtained in Colorado corroborate the tests taken in Pittsfield, where an apparatus, consisting of a rod parallel to a plate, was tested for corona during the period of a month. The voltage at which luminous corona appeared remained constant although the vapour product varied from 0·36 to 1 and the relative humidity from 43·5 per cent. to 78 per cent. The barometric pressure varied between 28·7 in. and 29·2 in.

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

Fig. 3 shows the result of the measurements. An attempt was made to separate insulator losses from corona losses, but the insulator losses (which were measured in dry weather only) were so small that no definite measurement of their value could be obtained, and these are neglected in the following decision. The voltage at the lower end of the line was measured by using a step-down transformer, and was 2 per cent. higher than at Denver.

The measurements were taken as follows: The transformer only was connected to the system and readings taken, then the line was connected to the transformer and readings taken at the same voltages as before. The difference between the kilowatts in the two cases gives the total losses of the line.

The author then proceeds to discuss an equation representing the power losses and also the term "critical voltage."

THE EFFICIENCY OF METAL FILAMENT LAMPS.*

BY R. A. HOUSTOUN, M.A., D.SC.

Abstract.—The author, after discussing previous methods, describes a method of measuring the radiant efficiency of lamps, *i.e.*, the ratio of the luminous energy to the total energy radiated. Results are given for carbon, tantalum, tungsten and osmium filaments.

Engineers are accustomed to measure the efficiency of a glow-lamp in watts per candle; on the other hand, we may regard the lamp as an energy-transforming device and measure its efficiency by the percentage of electrical energy it transforms into light. Let Q be the electrical energy consumed per second, R the total energy radiated per second and L the total luminious energy radiated per second. Then we make the following definitions:—L/Q = luminous efficiency, L R=radiant efficiency of the lamp. R is always less than Q, as all the energy is not lost by radiation, but some by conduction and convection. This proportion is, however, so small that it is usually neglected (Dr. C. V. Drysdale has found the convection loss to be not more than 2 or 3 per cent. of the total energy consumed).

For the purpose of defining L, it is usual to take 760 $\mu\mu$ as the upper limit of the visible spectrum. The lower limit is immaterial; there is little energy in the violet and ultra-violet spectrum of glow-lamps. The luminous efficiency does not measure the commercial value of a lamp because the eye is very much more sensitive to green than to violet, and it is possible for one lamp to have much more energy in the spectrum than a second one, but yet to have that energy so disadvantageously distributed that the second produces a stronger effect on the eye. The luminous efficiency is of more theoretical interest. It tells us how much of our energy is wasted in dark heat and how far we can with advantage hope to improve our lamps. This paper describes some measurements made on the radiant efficiency of carbon, osmium, tantalum and tungsten glow-lamps.

The usual method of measuring the efficiency was the calorimetric one. The lamp was placed in a glass calorimeter and then in a similar vessel of oil, and from the difference in the rise of temperature, with the proper corrections, the percentage of light radiated could be calculated. The method is in principle bad; the whole energy and the dark heat are measured, and the light is obtained as the difference between two much larger quantities, both subject to considerable error of observation. Another method was to measure the total radiation by the thermopile. A water filter was then placed in front of the thermopile, and the radiation that penetrated through the filter measured. This was supposed to be light, and if we made a correction for the light absorbed in, or reflected by, the filter—which could easily be measured photometrically—the radiant efficiency could be obtained. The objection to this method is that the water filter does not absorb all the heat. A solution of alum is no better than water, as is popularly supposed to be.† Hence corrections were made for the dark heat transmitted by the water by means of solutions of iodine in carbon disulphide, which were supposed to absorb all the dark heat that did pass. The utter untrustworthiness of all such methods, however, been demonstrated by E. L. Nichols and W. W. Coblentz. They have shown that they give a value much too large. Of these methods, one consists in determining the energy radiated at different wave-lengths by means of the spectroscope and thermo-pile or bolometer and plotting it as a function of the wave-length, a method which was introduced by K. Angström.‡ This latter has been used with modifications to the case of the carbon glow-lamp by C. E. Mendenhall.* who obtained 2·8 as the radiant efficiency of the latter at its normal brilliancy. This, I think, is the only previous determination of the radiant efficiency of a glow-lamp to which exception cannot be taken on the point of method.

The method I have applied is, as far as I am aware, original, though it almost follows from the article of Nichols and Coblentz. It seems preferable to both the above methods. The radiation was first measured in the usual way by a thermopile and galvanometer with and without a 1 cm. thick water filter, and the percentage of total radiation transmitted through the filter determined. In this case the radiation from the whole lamp was received by the thermopile. A straight part of the filament of average brightness was then focussed by an achromatic glass lens on the slit of a spectrometer with glass prism which was furnished with a Rubens linear thermopile in place of the cross wires. The same water filter was placed in front of the slit and an energy curve of the filament taken through the filter. For the region of the spectrum for which water transmits, the absorption of light in the glass and the loss of light by reflection at the glass surfaces may be taken as independent of the colour. If the prismatic energy curve thus determined be taken and an ordinate set up at the point 760 $\mu\mu$, the area on the side of shorter wave-lengths divided by the whole area gives the fraction of the radiation transmitted by the filter, which is light. It is only necessary now to find what fraction of the incident light is transmitted by the water cell. This was done by measuring the transmission coefficient of the latter when filled with water with a spectrophotometer for four different points in the spectrum. The value found was 0·84. It is somewhat low, as the glass sides of the cell absorbed rather more than usual; it did not vary with the colour.

The following table gives some results obtained:—

Radiant Efficiencies in per Cent.

Volts.	250-volt. carbon (1).	250-volt. carbon (2).	250-volt. tungsten (3).	250-volt. tungsten (4).
184	1·40	0·72	4·96	5·98
216	1·97	1·48	7·42	9·02
250	3·42	2·42	7·60	9·39
270	3·95	3·43	8·06	9·59
	130-volt. tungsten (5).	130-volt. tungsten (6).	125-volt. tantalum (7).	125-volt. tantalum (8).
75	1·61	1·69	2·06	3·00
125	6·61	6·43	6·66	6·35
146·5	9·04	8·83	...	...
150	...	...	7·70	9·25

All the lamps except the osmium (see below) are well-known makes much in use at present. Lamps (1) and (2) were of different makes, the filament in (2) having a metallic lustre; (3) and (4) were the same make, (5) and (6) the same make, and (7) and (8) the same make. A 50-volt osmium lamp was also tested and gave a percentage efficiency of 2·17 at 30 volts, 3·84 at 45 volts, and 6·52 at 55 volts.

The figures in the table are probably accurate to 5 or 6 per cent. The difference in the behaviour of the 250-volt and 130-volt tungsten lamps is probably due to a different method of manufacture. If we calculate the radiant efficiencies of the different filaments at their marked voltage and take the mean, we obtain:—

Carbon	2·9 per cent.
Osmium	5·2 ,,
Tantalum	6·5 ,,
Tungsten	7·5 ,,

My value, 2·9, for carbon, agrees well with Mendenhall's 2·8.

RAIL-LESS ELECTRIC TRACTION IN BREMEN.†

At the present time there are two electric omnibus routes worked on the overhead system in Bremen. One of these is nearly 3 miles long, and forms an extension of a municipal tramway route, while the other crosses the Bremen tramway and railway systems at one or two points. They both, therefore, act as feeders to other means of transport, though in somewhat different ways.

Both lines are supplied from the Bremen tramways station, and are worked on the continuous-current system, the pressure being 550 volts. The price charged is 1·6d. per kilowatt-hour. The overhead lines on these omnibus routes are different from those on other systems, in that the wires are placed one above the other, 11 in. apart, the positive being underneath and the negative above. In

* Paper read before the Royal Society of Edinburgh.

‡ Angström has shown recently by R. A. Houstoun and J. Logie, "Phys. Soc. Proc.," 1902, that an aqueous solution of ferrous ammonium sulphate absorbs dark heat much more effectively than water alone while allowing light to pass. Nevertheless, it is not satisfactory enough as a means of separating the dark heat from the visible radiation.

this way the points of suspension, points, crossings and collectors are all simplified. The upper negative wire, which is earthed, acts as a protection against broken telephone or other wires. While the installation is agreeable to the eye in that the cars moving in either direction use the same source of supply, and only two wires in all are therefore needed. Cars meeting have, of necessity, to stop and change over the collectors, an operation which, however, takes only 12 to 15 seconds.

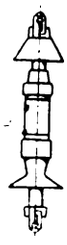

FIG. 1. DISTANCE PIECE FOR TROLLEY WIRES.

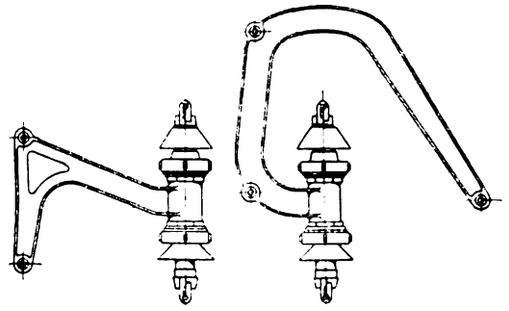

FIGS. 2 AND 3.—SUPPORTING ARRANGEMENTS ON CURVES.

The trolley wire is grooved, and is of 0·1 sq. in. in section. The supporting masts are placed 85 ft. to 100 ft. apart. Between the wires are placed separators (Fig. 1) in orde that they may be kept the proper distance apart. These separators consist of two insulator bolts fitted with terminals for the wires. The supports on the straight stretches consist of iron bows *b* (Fig. 4) with three fixing contacts for the wires. The two trolley insulator bolts, *u*, are placed upright in a coupling. They are e ch provided with a screwed cap, *v*. Each

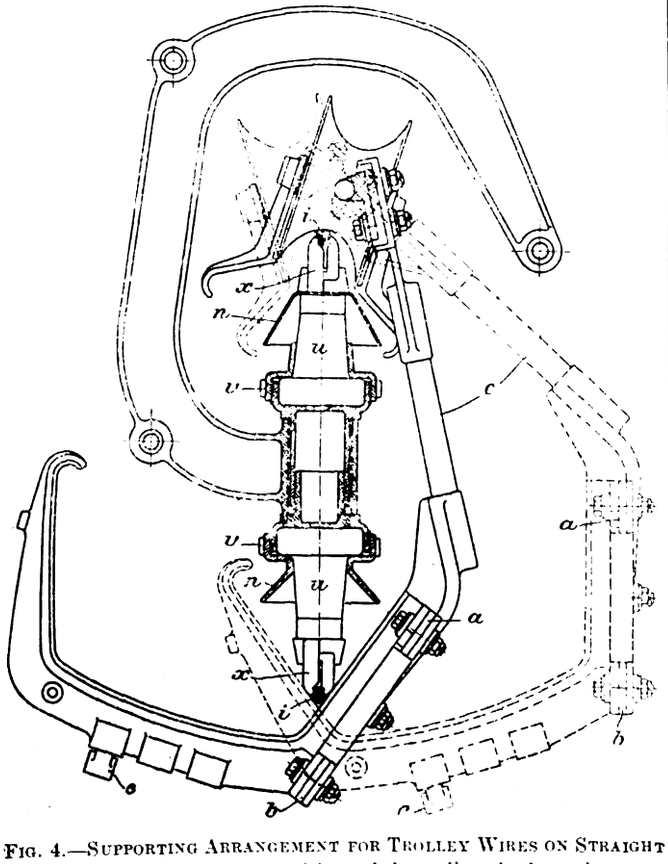

FIG. 4.—SUPPORTING ARRANGEMENT FOR TROLLEY WIRES ON STRAIGHT STRETCHES. The extreme positions of the trolley wheel are shown.

insulator bolt is protected by a covering, *w*. At the end of these bolts are fixed terminals, *x*, into which the trolley wire, *i*, is screwed. Between each span wire and the pole is placed an insulator, so that double insulation is provided between the positive and earth. Figs. 2 and 3 show the suspensions used on curves. Lightning arresters are placed in the positive wire every 1,000 yds., while the negative is earthed at equal intervals. Fig. 6 shows the arrangement employed on the overhead work where the omnibus route crosses the tram system. For a distance of 12 ft. on each side the crossing point both systems are rendered dead by the insertion of section insulators in the case of the tramways, and by breaking the trolley wires of the omnibus routes by means of several insulating buckles. As shown in Fig. 6 the trolley on the tramway has to pass over an open space of about 1¼ in. at *c*, where the wire is broken. This space has to be left for the trolley arm of the omnibus to pass through. The trolley arm employed on the omnibus routes is of the combined bow and wheel type, and its construction is shown in Fig. 5. The springs allow it to move up and down, as the height of the trolley wire varies. In order that the trolley can be quickly removed when necessary, a vertical pole is arranged at the front of the car near the driver's platform. This is movable round a horizontal axis, and supports the cable on its way to a drum, which drum is placed near

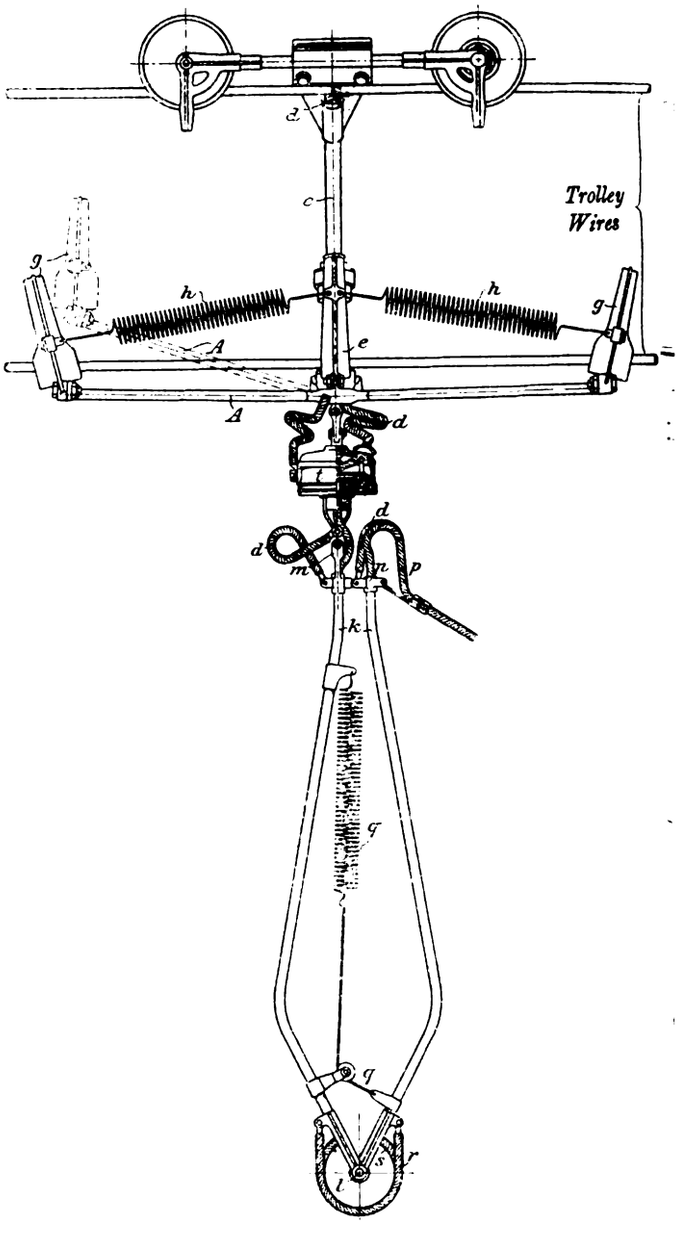

FIG. 5.—CONSTRUCTION OF THE COLLECTOR.

the front part of the car and winds the cable in or out automatically by means of a special spring arrangement. The current is then conveyed to the motors through two rubbing contacts. When two cars meet each driver, by means of a handle, can draw down the cable loop so that the cable can be uncoupled from one and coupled up to the other collector.

The cars used are about 20 ft. long, 10 ft. high and 8 ft. broad. They have seating accommodation for 20 passengers, and for standing; they weigh 3·2 tons empty.

The electrical equipment consists of an 18 H.P. interpole motor which can exert 35 H.P. if required. It runs at 650 revs. per min. and drives the rear axle through a cardan link and differential gear. The controller has five working and two braking positions. A foot-brake is also provided. For trailer working a special contact is fitted to the

Digitized by Google

foot-brake lever, whereby current from the overhead line can be supplied to the trailer brakes. The lighting of the car is carried out by glow lamps.

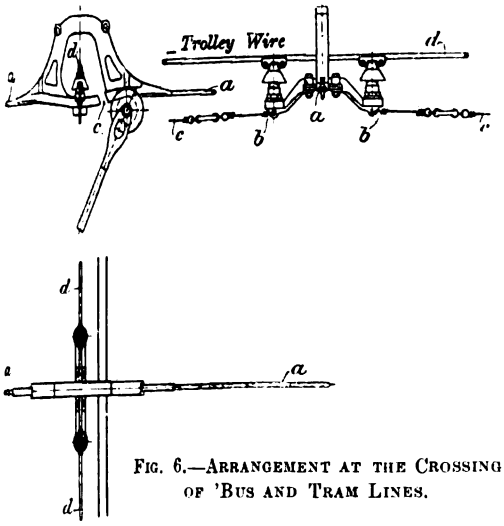

FIG. 6.—ARRANGEMENT AT THE CROSSING OF 'BUS AND TRAM LINES.

The energy consumption per car-mile including car, waiting room and shed lighting, as well as shunting, works out at about 560 watt-hours or at from 88 to 112 watt-hours per ton-mile.

THE PROPAGATION OF MAGNETIC WAVES IN AN IRON BAR.

BY C. V. DRYSDALE, D.SC.

Summary.—It is pointed out that there is a close analogy between the propagation of alternating magnetism along an iron bar and that of alternating current along a cable. Experimental results are given confirming this analogy, the measurements being made with a search coil and the author's alternate-current potentiometer.

In a series of articles published in THE ELECTRICIAN about three years ago* the writer gave a summary of the elementary theory of alternate-current transmission in electrical circuits, with diagrams showing the theoretical variation of P.D. and current along lines of different characteristics. Later, when the alternate-current potentiometer was developed,† it was pointed out that these results could be easily checked by experiment, and experiments are in progress with this object. But one of the most useful applications of the potentiometer is to the exploration of alternating magnetic fields by the aid of a search coil, and a simple illustration of this is given by the distribution of magnetic flux in a long iron bar magnetised at one end by a coil fed with alternating current. The result is that magnetic waves are propagated along the bar according to a law resembling that of the transmission of electrical waves in cables, and the variation of the flux vector from point to point can be easily determined by a search coil enclosing the bar and connected to the potentiometer.

The theory of this transmission is as follows: In Fig. 1 let PQ be the iron bar and C the magnetising coil. If we consider two sections of the bar at distances of x and $x+\delta x$ from the further or receiving end, we have $\delta V = \frac{1}{\mu} B \delta x$, where B is the induction density and δV the increment of magnetic potential. This is on the assumption that there are no eddy currents in the bar; but, if there are, their magnitude may be taken as proportional to the induced E.M.F. or to $\dot{B}$,* and also their demagnetising effect. Hence we must write $\delta V = \frac{1}{\mu} B \delta x + K \dot{B} \delta x$, where K is a coefficient depending upon the section of the bar and the conductivity of its material, or $\frac{\partial V}{\partial x} = \frac{1}{\mu} B + K \dot{B}$. At the same time there is a magnetic leakage or dispersion from the sides of the bar which we may take as being proportional to the magnetic potential V, and hence $\delta B = K' V \delta x$, or, $\frac{\partial B}{\partial x} = K' V$, where K′ is a coefficient depending on the reluctance of the return path of the flux through the air.

We may now compare the equations for the bar and cable as follows:—

Magnetised bar.		Cable.
$\frac{\partial V}{\partial x} = \frac{1}{\mu} B + K \dot{B}$	.....	$\frac{\partial V}{\partial x} = rC + L\dot{C}$
$\frac{\partial B}{\partial x} = K' V$	.....	$\frac{\partial C}{\partial x} = gV + K\dot{V}$

By comparison it will be seen that the magnetised bar is the analogue of a current carrying cable in which the resistance corresponds to the recipocal of the permeability, the inductance to the eddy-current coefficient, the leakance to the dispersion coefficient; and having no capacity.

FIG. 1.—ARRANGEMENTS FOR TEST.

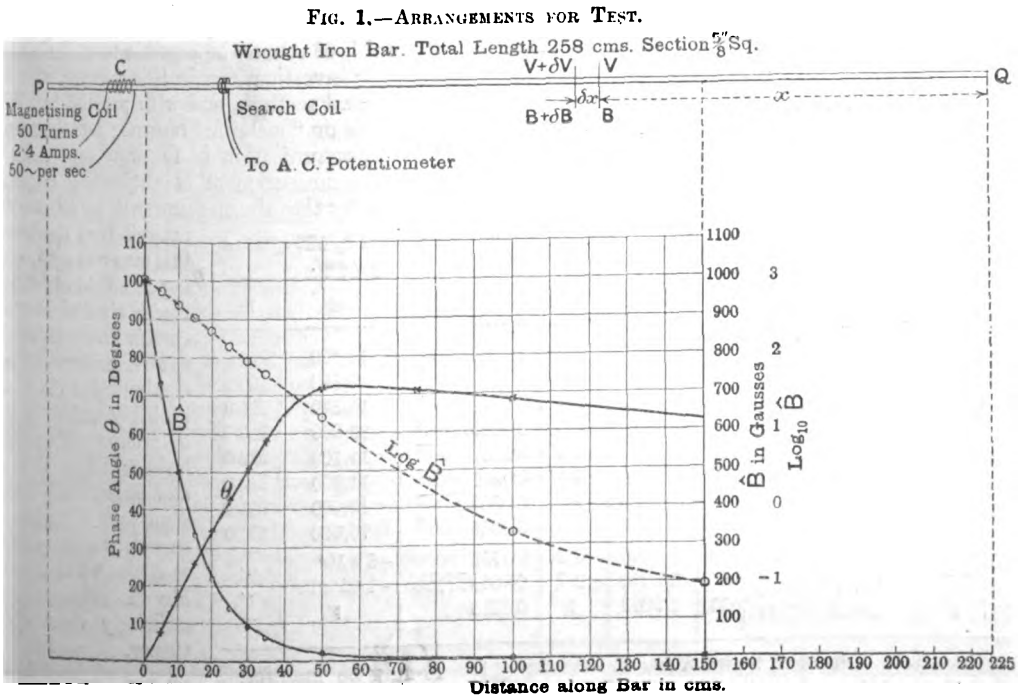

FIG. 2.—CURVES OF FLUX DISTRIBUTION.

* This is not rigidly true, owing to inductance, but is probably sufficiently close at ordinary frequencies. The effect of hysteresis would also be to cause a lag of the flux.

* "The Theory of Alternate-current Transmission in Cables," Dec. 6, 1907—Jan. 10, 1908.

† "The Use of the Potentiometer on Alternate-current Circuits," Phil. Mag., March, 1909.

Digitized by Google

It will further be noticed that if we consider a cable with negligible inductance, the two sets of equations correspond exactly in form, if we take the magnetic induction as corresponding to the electric potential, instead of to the current.

It is of little use attempting to establish an accurate formula suitable for numerical calculation, as the permeability and dispersion are both very indeterminate; but we may expect the flux vector to vary in somewhat the same way as the P.D. vector in the case of an ordinary cable, except that the attenuation constant must be extremely large, owing to the low magnetic "insulation resistance." If the bar is sufficiently long the flux in the portion near the exciting coil should vary approximately according to the law $B = B_0 e^{-ax}$, where x is the distance measured in the direction of propagation from the point at which the induction is B_0 and a is the attenuation constant, which may be written either in the form $a\,\alpha$, or $b + jc$.

Experiments.—The bar used for this experiment was an ordinary length of square wrought iron, $\frac{3}{8}$ in. square and about 8 ft. 6 in. long. This was magnetised by a coil of about 50 turns, through which a current of 2·4 effective amperes at 50 ~ was steadily passed. Search coils of 100 or of 1,000 turns were connected directly to the potentiometer, and the bar was marked off in equal intervals, at which the search coil was successively placed. The potentiometer reading gave the effective E.M.F. vector at each position directly, from which the vector of maximum induction $\hat{B}$ was calculated by the relation $\hat{B} = \frac{\sqrt{2} \times 10^8 E}{Apt}$, where E is the effective E.M.F., A the area of section of the bar in square centimetres, $p = 2\pi n$, and t the number of turns in the search coil. In order to obtain the real attenuation constant b, we have $\hat{B} = \hat{B}_0 e^{-bx}$ from which $\log_e B = \log_e B_0 - bx$, and $b = 2{\cdot}3026 \frac{\log_{10} B_1 - \log_{10} B_2}{x_2 - x_1}$, while $\alpha = \frac{\partial\theta}{\partial x} = \frac{\theta_2 - \theta_1}{x_2 - x_1}$, and $a = \frac{b}{\cos \alpha}$, the attenuation constant thus being given in the form $a = a\angle\alpha$. Lastly, the velocity of transmission of the magnetic waves is easily calculated, for since there are 360 degrees of phase angle to each period, and n periods per second, the angle phase changes by $360n$ degrees per second, and as α is the number of degrees of phase lag for 1 cm. displacement along the bar, the velocity of propagation in centimetres per second is $v = \frac{360n}{\alpha}$. Similarly the wave-length in centimetres is $\lambda = \frac{360}{\alpha}$.

The following table gives the results of an experiment, the first three columns being observations, the remainder being calculated from them as above:—

Wrought Iron Bar 258 *cm. long,* $\frac{3}{8}$ *in. sq. Area of cross section* = 2·52 *sq. cm. Magnetised by* 120 *effective ampere-turns at* 50 ~ *per second. Distances measured from end of magnetising coil.*

1,000	35	0·3325/58°	60·1	1·7739	15	0·5604	3·6	0·0860/0·24°	75,000	1500·0
1,000	50	0·0915/71·6°	16·4	1·2135	25	0·8645	−0·9	0·0795/0·036°	-5×10^5	...
1,000	75	0·0125/70·7°	2·23	0·3490	25	0·6990	−2·7	0·0643/0·108°	$-1{\cdot}66 \times 10^5$	...
1,000	100	0·0025/68°	0·417	1·6600	50	0·6889	?	0·0318	?	...
1,000	150	0·0005/ ?	0·089	2·9511						

It will be seen that the values of $\hat{a}$, v and λ are at first fairly constant, and the mean values for the second to the sixth reading are $\hat{a} = 0{\cdot}0842\angle 1{\cdot}72°$, $v = 10{,}460$ cm. per second, and $\lambda = 210$ cm. As the angle α is so small, cos α is practically unity, and the values of the vector and real attenuation constants are sensibly equal. Beyond 35 cm. from the coil the phase angle ceases to increase at the same rate, and it afterwards actually decreases. This might be ascribed to reflections from the further end of the bar, but in view of the heavy attenuation and the distance of the free end, this can hardly be the case. In an earlier experiment, under nearly the same conditions, the same effect was found to an even greater extent, but in this case a large iron stanchion was near to the bar about half-way along its length.

In Fig. 2 the values of $\hat{B}$, log $\hat{B}$ and the phase angle θ are plotted along the bar, and it will be seen how the values of log B and of θ lie almost exactly on a straight line at first, in accordance with theory, while the phase angle at first increases in proportion to the distance, becomes a maximum at about 6·0 cm. and then diminishes.

Fig. 3 is a polar or vector diagram of the flux vectors, which should be compared with the theoretical curves given for cables in the Paper above referred to. It should be pointed out that the *vector differences* between successive flux vectors represents the magnitude and phase of the total leakage flux in the interval, and the dotted polar diagram or the "hodograph" of the longitudinal flux represents the leakage flux obtained in this manner. It also, probably, represents approximately the distribution of magnetic potential along the bar, which could also have been directly measured by winding a second search coil on a long iron rod held close to and perpendicular to the bar under test. This rod would, however, have disturbed the magnetic distribution in the test bar, in the same way as a low resistance voltmeter would disturb the distribution of potential in a cable.

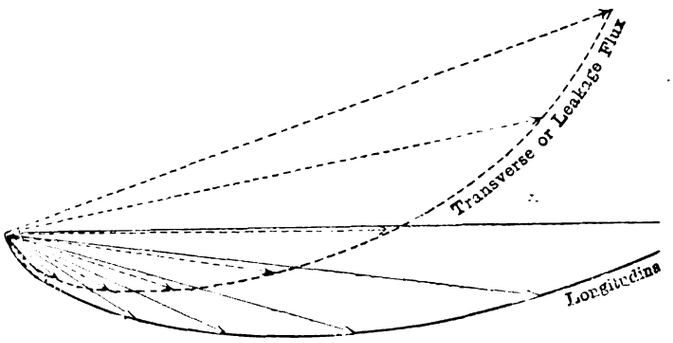

FIG. 3.—VECTOR DIAGRAM OF FLUXES.

It would, of course, be possible to make a number of most interesting investigations in this manner, with bars of various materials and sections, and with parallel bars laid by the side as magnetic or "metallic" returns; but the main object of the present communication is to show how easily problems involving the measurement of alternating magnetic fields may be solved by the alternate-current potentiometer. It will be noticed that the lowest reading in this case was $\frac{5}{10000}$ volt, corresponding to a field of 0·089 gauss, or half the horizontal component of the earth's field. In the case of alternators, motors and transformers, a single loop of the finest wire would probably suffice in most cases to determine either the working or leakage fluxes both in magnitude and phase. It is hoped to publish some tests of this kind very shortly, as well as some tests on propagation in cables, which have been made by Mr. H. Tinsley, and which are in strikingly close agreement with theory.

It may be mentioned that the whole of the arrangements for the above tests, with the observations, were made in about three hours. Some of the measurements were made by the writer and some by Mr. Tinsley with perfect agreement. The values given in the table are from a set of readings by Mr. Tinsley, to whom the writer is indebted, not only for facilities and help in the tests, but for the excellent manner in which he has constructed the alternate-current potentiometer and its accessories.

CAST COPPER OF HIGH ELECTRICAL CONDUCTIVITY.*

BY E. WEINTRAUB.

The production in the foundry of pure copper castings mechanically sound and possessing an electrical conductivity comparable with that of pure forged copper has been an important problem ever since the development of electrical machinery and apparatus. The cause of the difficulty has been sufficiently well understood for a long time. Molten copper has the property of dissolving gases and of giving a part of these gases free on cooling. This produces pinholes and even big cavities. The casting obtained is therefore mechanically unsound, and has naturally a low electrical conductivity.

The elimination of these dissolved gases presents but little difficulty. It is sufficient to add one of the well-known deoxidisers, but the electrical conductivity of the copper thus produced is, however, as a rule, low, because all the *deoxidisers used have also the property of combining with copper*, and the remarkable rate in which the conductivity of copper drops when small amounts of impurities are alloyed with it is well known. The amount of the gaseous oxygen occurring dissolved in copper during the process of melting is a negligible quantity and is distributed throughout the whole mass. It is therefore practically impossible to add the deoxidiser in such a way as to eliminate oxygen completely without, at the same time, alloying it to a certain degree, with the copper. Accordingly, the conductivity of the resultant product was a matter of accident. In the laboratory sometimes good results were obtained, but they were hard to duplicate, and the transfer to the foundry was always a disastrous experiment.

While carrying on the work of the isolation of the pure element, boron, and its fusion, the lack of affinity of this element for copper forcibly impressed itself on my mind. Boron has, at the melting point of copper, a great affinity for oxygen, nitrogen, &c., and it occurred to the author, therefore, that boron ought to be the ideal substance for deoxidising copper.

The boron as prepared by methods described by me in paragraphs 3 and 4 of my article* can, by this time, be produced in large quantities, and is rather inexpensive for uses based on its electrical properties. For casting copper, however, its price would probably be too high. In the course of the investigation mentioned the author had prepared, as we saw, an amorphous powder which contained as essential impurity only a certain percentage of oxygen, and which was termed "boron suboxide." This substance is prepared by a modification of the reduction process of boric anhydride by magnesium. Obviously for the purpose of eliminating oxygen from copper without introducing any impurity capable of alloying with copper, this boron suboxide would be as good as pure boron, or perhaps better, on account of its being obtained in form of a very fine powder.

This substance was used in the first experiment. The very first heat was successful. A perfectly sound bar was obtained with a conductivity of 94 per cent.; 0·1 per cent. of the weight of the copper was added. Further experiments showed that the amount of boron suboxide could be reduced to 1·30 of 1 per cent., and also that the presence of a large excess, say, of 1 per cent., did not diminish the conductivity or change in any way the mechanical properties of the cast copper.

A further simplification could, however, be introduced into the process. The reduction of boric anhydride by magnesium, the first being in excess, gives a product containing magnesium borate, boric anhydride and boron suboxide. While the last one is the active agent, the first two are harmless. In fact, the presence of boric anhydride and magnesium borate is even an advantage, as the addition of a larger mass of material makes the operation easier; and as boric anhydride would probably dissolve the copper oxide and bring it to the surface as copper borate. It is therefore unnecessary to submit the direct product of the reaction to chemical treatment for the purpose of isolating the boron suboxide. It is sufficient to grind up the mixture into coarse grains and use an aliquot part of it which contains the necessary amount of boron suboxide. The foundry practice at present is to add 1 per cent. to 1½ per cent. of this material, which is equivalent to 0·08 of 1 per cent. to 0·1 per cent. of boron suboxide.

The properties of the material obtained are as follows: The electrical conductivity obtained can be as high as 97½ per cent. if the copper melted down is perfectly pure. In the foundry, where the scrap copper which is melted down cannot always be very carefully selected, a conductivity of 91 to 95 per cent. is obtained, and a conductivity of 90 per cent. is at present given. The resultant casting can be easily machined; fears which were entertained on this subject did not materialise, and the engineers using the material have not complained on this account. The mechanical properties are as follows:—

Tensile strength.	Elastic limit.	Elongation.	Red. in area
24,350 lb. per sq. in.	11,450 lb. per sq. in.	48·5%	74·49%

Castings are being made of all shapes and sizes with no more difficulty than in the case of brass. Sand and iron moulds can be used, and for standard articles the latter are preferred.

The use of cast copper is spreading as engineers get better acquainted with it, and is already of very considerable magnitude. It is interesting to note that, in spite of the fact that cast copper has lower conductivity than forged copper, in many cases, as, for instance, in case of current transformers, the effect of higher conductivity is obtained by substituting it for forged copper. This is due to the fact that in casting a chance is given to eliminate riveted, screwed or soldered joints, whereby a number of poor contacts are avoided. Not only this, but the elimination of joints often ensures a better operation.

The cost of the boron added is small; at the present prices of magnesium and boric anhydride, the cost per pound of copper is rather over ¼d.

* Abstract of a Paper read before the American Electrochemical Society.

† "Transactions," American Electrochemical Society. 16, 165 (1909).

BREAKING HIGH AND LOW POTENTIAL CIRCUITS.

At the annual general meeting of the South Wales Institute of Engineers, held at Cardiff on the 20th inst., the discussion on Mr. A. G. Collis's Paper on the above subject was concluded. An abstract of the Paper and the earlier portion of the discussion were given in our issues of March 10th and 17th.

At the meeting last week a communication was received from Mr. A. M. TAYLOR (Birmingham Corporation Electricity Department) in which he pointed out that the operation of the switch designed by him was so rapid that, when it operated on alternating currents, the period over which it acted was so short that the current could be considered uni-directional over the period considered, and therefore the action of the magnetic blow-out was as effective in quenching the arc as on a direct-current circuit. Reference had been made to the effect of the arc from the magnetic blow-out upon the oil. Whatever this might be, it was more than counter-balanced by the rapid displacement of the oil effected by the movement of the switch block in the oil. Diagram 33 of Mr. Collis's Paper showed the effect of opening on 200 amperes. If the current had been 2,000 amperes the contacts would have had to open more widely before the circuit was interrupted. He had found that in two leading makes of oil switch gaps of 1 in. and 1½ in. were attained before circuit was broken, the switches moving at a velocity of 4½ ft. per second and 2 ft. per second respectively. Without considering the damping effect of the oil and the friction of the parts, which would extend the time of opening, the times taken would be 0·036 and 0·042 seconds respectively and he therefore doubted if Mr. Collis's figure of 0·01 second was accurate. If it was, he thought he must have had special means of opening. The time would be extended if the switch were operated with the long rods and cranks necessary for medium-distance control. Mr. Collis had disagreed with him in his previous reply to the discussion, instancing a circuit-rupture on a 6,000-volt cable with 500 amperes, the length of the feeder being about 200 yds., where a rise of 9,300 volts was obtained. He did not know whether the switch had only to deal with the self-induction of the cable or whether a motor was in circuit. But if a pure short-circuit occurred across a cable a rise of volts could be produced on the generator greater than the voltage of supply, the voltage of the generator at the instant of rupture being dependent on the rise of current at that instant. If, by inserting resistance in the switch at that time, the rate of current rise could be lowered, it was obvious that the reactance voltage of the generator would be correspondingly reduced.

Mr Collis being prevented from attending the meeting, the discussion was closed, subject to a written communication from Mr. Collis being incorporated in the "Proceedings" of the Institute.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 10s nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS By R. Livingstone. Price 6s. nett

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming. M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. A COMPLETE TREATISE. *Ready in April.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Höener, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

STAMPING OF ELECTRICITY SUPPLY AGREEMENTS.

The extraordinary development in the application o electrical energy to power purposes during recent years particularly since the commencement of supply by electric power companies over large areas, has brought in its train the necessity for some change in the terms and condition under which a supply is given. In the earlier days of the industry, when electricity was almost entirely used fo lighting, a supply was usually given by the undertakers upon receipt of a form of application signed by the intending consumer, who undertook to pay at a certain rate (usually a flat rate per unit) for the energy supplied. The cost o service mains, with the necessary meter and service equipment, for a lighting supply is not, as a rule, an expensiv matter once the general system of distribution mains ha been laid, and the supply authorities usually do not conside it necessary to enter into a formal agreement, as they ar practically assured of the continuance of the demand for supply so long as the premises are tenanted.

The supply of electricity in large quantities to textil manufacturers, to collieries, and to other large users of power

Digitized by Google

however, is another matter, as a considerable capital expenditure is usually entailed, and the simple form of application for supply no longer meets the case. The supply authority must be assured of a reasonable return on the capital expended, and the practice is becoming general of entering into formal agreements under which the consumer agrees to guarantee a minimum revenue per annum for a period of years, a condition which is readily agreed to by power users. Under these circumstances the stamping or non-stamping of such documents is of considerable importance to the industry. The Stamp Act of 1891 provides that agreements in writing not specifically charged with any duty shall be subject to a stamp duty of 6d. each, but agreements relating to the sale of "goods, wares or merchandise" are exempt from duty, unless the agreement is under seal when the duty is 10s. It will be noted that this exemption only applies to agreements relating to the sale of "goods, wares or merchandise," and it may be somewhat of a surprise to find that until 1909 the Commissioners of Inland Revenue held that, whilst agreements for the sale of gas and water were within the exemption, stamp duty was held to be payable on agreements for the sale of electricity, the latter *not* being considered as either goods, wares or merchandise. By sec. 19 of the Electric Lighting Act, 1909, electrical energy is now to be deemed "goods, wares or merchandise" for the purposes of sec. 59 of the Stamp Act 1891, though the better legal opinion is that sec. 19 merely stated in set terms the law as it existed. The point, whether "electrical energy" is goods is, therefore, no longer of importance.

However, the payment of a duty of 6d. or 10s. is now considered sufficient by the Inland Revenue authorities in the case of agreements for the sale of energy where a minimum payment per annum is guaranteed, or where a minimum quantity of electricity must be taken, such agreements being held to come under the heading of "bond, covenant or other instrument being the only or principal or primary security for an annuity or for any sum or sums of money payable at stated periods," and a stamp duty of 2s. 6d. is exacted for every £5 or fractional part of £5 of the annual payment guaranteed; that is to say, if an agreement is made for the supply of electrical energy for a minimum payment of £1,000 per annum (an unreasonable or unusual guarantee in these days of cheap power supply) such an agreement must be impressed with an *ad valorem* stamp of £25, an amount equivalent to 2½ per cent. on the revenue guaranteed for the first year. Agreements of this character came before the Courts for consideration in February, 1909, when Mr. JUSTICE CHANNELL decided in his judgment in the case of the "County Durham Electrical Power Distribution Co. *v.* The Commissioners of Inland Revenue" that, although he had a strong impression that such a document as the one before him was not of the kind contemplated by the Legislature when it inserted the clause in the Stamp Act, and although the question of the Crown was a far-reaching one, he considered he was bound by judgments of the House of Lords and Court of Appeal in other cases and, therefore, he must find for the Crown. At the conclusion of the case it was stated by the Solicitor-General that "it is not the practice of the Inland Revenue officials to insist upon the *ad valorem* duty in the case of ordinary commercial documents," a statement which makes it difficult to understand why agreements for the sale of gas or water should have been exempted whilst agreements of a similar kind for the sale of electricity were charged with stamp duty.

In the course of the delivery of legal arguments, the question was raised whether electricity was "goods, wares or merchandise," and the Solicitor-General, who appeared for the Crown, expressed himself ready to admit that it was, but he contended that, nevertheless the form of agreement used by the County of Durham Co. was such that it would come under another section of the Stamp Act, and that it would fall under the category of "bond, covenant or instrument of any kind, &c.," and was, therefore, liable to duty as set out in the first schedule to the Stamp Act, 1891. The Company appealed, but the Court of Appeal upheld Mr. JUSTICE CHANNELL's decision, being bound by judgments of the House of Lords in the case of the "Sweetmeat Automatic Delivery Co. *v.* The Commissioners of Inland Revenue," a case of an agreement with a railway company to allow automatic machines at railway stations for an annual payment of £3,000; and the "National Telephone Co. *v.* the Commissioners of Inland Revenue," an agreement in writing (not under seal) whereby the Company, in consideration of an annual payment of £12, undertook to maintain a private telephone service. These cases differ widely from the Durham case, and we are not surprised that Mr. JUSTICE CHANNELL, who is without doubt one of the ablest and most impartial judges on the Bench, should be reluctant to treat as a bond, covenant, or security, an agreement (not under seal) for the supply of electricity, containing what is known as a "minimum clause." In law the Durham agreement was certainly not a bond or covenant, and it is difficult to see where the security comes in. There is no analogy between an agreement for the sale of electricity and a lease of railway premises or an agreement for the maintenance of a telephone service. Moreover, no rational distinction can be made between the cases where a flat rate and a differential rate of charging for energy is adopted. Supposing A and B, two intending consumers of electrical energy, desire the local electricity undertakers to give a supply up to a maximum of, say, 50 kw. By the Electric Lighting Acts, 1882 to 1909, each is bound to declare his probable maximum demand, and to supply other information to the undertakers. It is found that the demand of A, which is mainly for lighting, can be anticipated, and therefore, he is charged at the rate of 4d. per unit; but B requires energy for power and heating, and, as the load may vary a good deal and the demand be intermittent, the undertakers, wishing to make a safe, commercial bargain, charge him £150 per annum, and ½d. per unit for all energy consumed. Further, we cannot see any difference in principle between the case of B and, say, an agreement for the sale of goods to be paid for by instalments, or a contract by one man with another for the purchase of future goods, *i.e.*, goods to be manufactured. The purchaser agrees, say, to buy a quantity of cloth at a certain rate per yard, but he

Digitized by Google

has the option of taking a larger quantity at a discount of 10 per cent. off the stated price. In the two last mentioned cases there would be no need to stamp the agreements, but the agreement with B would require a stamp of £3. 15s. Apart from the trouble and inconvenience of stamping agreements that are entered into daily, it is quite a tax—and an unfair tax—on a comparatively new but rapidly developing industry, which is hampered in other respects by restrictive legislation. The demand for electrical energy for power, heating and domestic purposes is increasing at a rapid rate, and it is necessary that electricity undertakers should have freedom as to the terms upon which they are to give a supply. In many agreements it is usual to insist upon a minimum clause, and it is immaterial whether this takes the form of a minimum payment of money, or a minimum quantity of energy (at a certain rate per unit) to be taken by the consumer, for in the latter case the amount of the periodical payment can be calculated.

It is, therefore, an important matter for the electric supply industry, and every effort should be made to get all agreements for the supply of electricity placed in the same position as agreements for the sale of goods. A remedy could be provided by the insertion of a clause in the annual Finance Act, and we hope that the Municipal Electrical Association, the Electrical and Allied Trades Section of the Chamber of Commerce, the Association of Electric Power Companies, and others interested in electricity supply, will take up the question with energy and cause representations to be made to the Chancellor of the Exchequer in order to induce him to remove a tax which is a serious restraint on trade.

LARGE POWER FITTING-OUT CRANES, WITH SPECIAL REFERENCE TO ELECTRIC REVOLVING CANTILEVER CRANES.*

BY ROBERT BOYLE, B.SC.

One of the chief features which have marked the early years of the twentieth century is the rapid increase in the size and capacity of ships, and, consequently, in the appliances for their equipment. This has necessitated cranes capable of handling much heavier loads, and shop cranes are now in hand by British firms with a lifting capacity of 200 tons. Fitting-out cranes of similar capacity are also required to transfer such a load to the ship itself. It behoves the engineer and shipbuilder to be well in advance with schemes for dealing with the largest loads. Such design must necessarily be in advance of the ship itself.

It is a significant fact that the Admiralty have at present under consideration tenders for a new crane of the revolving cantilever type for Portsmouth dockyard, capable of lifting a working load of 240 tons at 105 ft., with a test load of 300 tons at the same radius, and a minimum clearance of 140 ft. from quay level to underside of jib. Two floating cranes of 150 tons capacity are likewise under consideration.

The author proceeds to discuss fitting-out cranes of large capacity for shipyards, wharves and quays. After giving particulars of installations of derrick cranes, fixed portal jib cranes, Fairbairn cranes and sheer legs, he considers floating cranes and mentions that steam as a motive motor is almost universally used for these. Increased efficiency would accrue from the use of electrical instead of mechanical power, but it is difficult to apply in practice, and the working of these cranes is largely intermittent. After discussing the advantages and disadvantages of floating cranes as compared with giant cantilever cranes, large tower cranes are next dealt with.

Tower cranes of large capacity may be divided into three main types:—(*a*) Hammerhead cranes (mostly German designs); (*b*) giant electric revolving cantilever cranes (British designs); (*c*) hammerhead derricking cranes. These are all of the cantilever type. The first large cranes erected in this country were of the German hammerhead type, but at the present time the large cantilever crane is the most popular. A list of most of those already erected by British firms and by German firms in Britain is given in an appendix to the Paper. When fitted with propelling and revolving machinery the cost of a floating crane is almost double the price of a cantilever crane of equal capacity, but each case must be considered on its merits in choosing any particular type of crane.

The hammerhead cranes consist essentially of a double-armed, horizontal, revolving, cantilever jib, supported by a revolving latticed crane post, the whole resembling in shape a hammer. The crane spindle usually turns in a cylindrical bearing or foot-step, set in solid masonry, and is supported by a framework either trilateral or quadrilateral.

The form of tower which seems to commend itself most where there are no special reasons for the contrary, is the truncated trilateral pyramid, first applied by Messrs. Bechem & Keetman to a 150-ton crane at the Krupp "Germania" yard, near Kiel. By placing two of the legs at the edge of the quay the traffic can be led on both sides of the centre post, under the framework.

The British type of giant cantilever crane consists essentially of a long horizontal slewing jib, with unequal cantilever arms tied in position by a centre pivot, and capable of rotating in either direction through 360 deg. on a ring of live conical steel rollers, which rest on four strong platform box or lattice girders at the top of a square steel latticed tower. The machinery house containing the hoisting gear and brakes is placed over the counterweight box at the extreme back end of the cantilever, and a crab, or trolley, which may be self-propelling or driven from the machinery house by racking ropes led to the jib-head, travels along the long arm.

The efficiency of the modern cantilever crane is largely due to the adoption of electric power. The introduction of the electric motor has made it a success, which steam and hydraulic power could never have done. The various units in the power system may now be quite separate and disconnected, and may be placed in the position of greatest advantage. The work required from a motor for crane work is of a very intermittent nature. The controlling element is the ratio between the period during which power is given out and the period for which the motor is stationary. A motor is required which will work under the given conditions without overheating or sparking, and this determines the size. For the smaller types of wharf crane this ratio may be an average of about 1 to 8. With large cranes, however, the length of run is a very important consideration affecting the size of the machine. The period of work may be so long that a motor has more than time to heat up before there is an opportunity, however long, for it to cool down. The rise in temperature should not be greater than about 75°F. The rating should be based on the load-factor to which the motors are subjected. In general, a one-hour rating will be found ample for motors and electromagnets for brake-releasing. In hoisting with a cantilever crane, from 20 to 30 minutes may be spent in continuous running before the motor has a period of rest, when slewing or racking would commence. There are, therefore, two main considerations in selecting a motor—(*a*) the maximum period of full work without stoppage, (*b*) the intermittency of the working. All motors, especially those used for slewing, should be capable of standing very heavy starting torques.

The complete cycle of operations necessary in a giant cantilever crane are:—(*a*) adjusting and slinging the load; (*b*) hoisting; (*c*) racking; (*d*) slewing; (*e*) lowering; (*f*) releasing the slings; (*g*) hoisting the empty hook; (*h*) racking back, if necessary, and slewing the jib into the housed position. The controllers for slewing and racking are sometimes made with the same number of points of control on each side, while those for hoisting have a larger number on the lifting side than on the lowering side. The regulating resistances may be of the grid type, or a special form such as Messrs. Siemens brick type, which is used for all except the main hoist motors for the 100-ton electric crane of the Port and Docks Board, Dublin. The operator's cabin in most of the British cranes is placed at the level of the drum girder, and between the main girders of the long arm of the jib at its inner extremity. In the Admiralty crane for H.M. Dockyard, Devonport, however, the operator's cabin is placed at a height of only 25 ft. above ground level within hearing distance, where a nearer view is obtained of the slinging of the load. The cabin rotates with the jib, and is cantilevered out from a central revolving steel latticed mast which is connected to and turns with the centre pin, which is rigidly attached to the jib. A simple switchboard is provided with an iron frame, and a double-pole switch and two single-pole fuses for each motor. Each motor circuit and all electrical devices are better safeguarded against short-circuits and overloads by enclosed fuses or circuit-breakers.

*Abstract of a Paper read before the Institution of Engineers and Shipbuilders in Scotland.

[redacted]

Electrically-controlled brakes, worked automatically by a solenoid, are usually provided on each motion. They are designed to hold the load should the current at any time be accidentally cut off. The greatest care should be taken to ensure that the braking appliances on all motions are good, and two independent brakes at least should be fitted on the hoisting machinery. The four types mostly used for the main hoist are:—(*a*) Electro-mechanical or solenoid; (*b*) mechanical or band; (*c*) rheostatic; (*d*) hydraulic. Brakes of these four types have been fitted by Messrs. Stothert & Pitt on two cranes on the Clyde, and two on the Tyne, built in conjunction with Sir William Arrol & Co., the designers of the structure. The mechanical or hand brakes, which can be worked by the foot in the driver's cabin, are capable of being used for any load. The electric brakes may be used for any load. The hydraulic brakes are used generally for the heavier loads from about 80 tons upwards. They are out of operation when lifting, but come into operation the moment the load tries to run back. Electric brakes depend for their action on the principle that when short-circuited by a variable resistance a mechanically-driven motor under certain conditions will generate current. The braking effort depends on the speed and resistance. The electric brakes are comparatively cheap, and give full control over the speed. An electric brake, however, can only act as long as the armature is in motion. The braking torque is applied directly to the armature of the motor. It therefore follows that should the gearing at any time give way, there would be nothing to keep the load from dropping. The same objection applies to the electro-mechanical brake provided with an electromagnetic release, as it is usually applied to the second motion shaft, or the shaft of the motor itself. These are essentially mechanical brakes of the band type, and are so arranged that the brake acts when the current is cut off accidentally or intentionally.

A typical equipment for a 150 or 200-ton crane would be as follows:—

Main Hoist.—Two motors with reversing switch. Nine points of control on both lifting and lowering sides, consisting of five series steps and four parallel steps. Overwinding switch operated by a cam on the main barrel shaft, giving an adjustable minimum distance of about 4 ft. between the two blocks. Rheostatic, hydraulic and band brakes.

Auxiliary Hoist.—One motor. Seven steps on hoisting side, and three for lowering on power. One free position, one "off" position, and four braking steps. Rheostatic and band brakes.

Main Rack.—One motor. Seven resistance steps out or in, one free position between power and braking, and three braking steps on both sides of barrel. The controller in this case is only fitted with a "dead man's handle." A switch is provided at minimum and maximum radius which operates a radius light, also a no-volt on the same switch. Rheostatic and band brakes on both sides.

Slewing.—One motor. Seven power steps and three braking steps on both sides, with a free position between power and braking. Rheostatic and band brakes on both sides.

Upper Hoist.—One motor. Five power steps on the hoisting side and two on the lowering side. Four braking steps with an intermediate position and a free position. Overwinding switch with an adjustable minimum of about 4 ft. between the two blocks. Rheostatic brake and "off" band brake.

Upper Rack.—One motor. Five points of resistance out or in. One free position and two braking steps.

The foundations, erection and testing of a cantilever crane are described in the Paper.

The author next considers hammerhead derricking cranes, which consist essentially of a pedestal derrick crane resting on a high tower, and combine some of the advantages of both the derrick and tower cranes. One of these cranes has been constructed by Messrs. Bechem & Keetman, for the Tranmere Bay Development Co., of Birkenhead. It is provided with electrically-driven hoisting, derricking, and slewing gear. It will lift 150 tons at 46 ft. on the large hook at 3 ft. per min., 50 tons at 82 ft. on the small hook at 19½ ft. per min., and makes a complete revolution in from 5 to 7 minutes. The total weight of structural steelwork is 305 tons, and the counterweight is 170 tons.

As in the case of the cantilever crane, the British type of the hammerhead derricking crane would be provided with a roller path at the top of the tower, and have no central revolving mast. A 150-ton electric pedestal derricking crane with revolving jib could be constructed for about the same price as a cantilever crane. It is believed that this type of crane will become more common, and it has many advantages.

The general principles of design of cranes are finally considered, and a design is given for a crane capable of dealing with a working load of 300 tons at 100 ft. and having a test load of 375 tons.

TEST ON 3,000 KW. TURBO-ALTERNATOR AT BRISTOL.

As the question of steam turbine efficiencies is very much to the fore, the results of the official tests of the first of the two new 3,000 kw. impulse type three-phase turbines built by the British Westinghouse Co. for the Bristol Corporation Electricity Department, may prove of interest as showing the efficiencies obtained on turbines of this type and size.

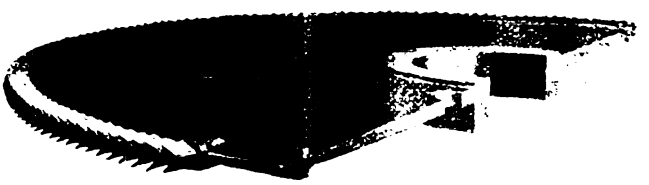

FIG. 1.—ARRANGEMENT OF BLADING.

The specified conditions of test were as follows:—

Normal output.—3,000 kw., three-phase, 50 periods, 6,000–6,600 volts. (The sets are designed for an overload of 25 per cent. for two hours, or 50 per cent. for short periods.)

Steam pressure.—200 lb. above atmosphere.

Superheat.—200° F.

Vacuum.—28 in. in relation to 30 in. barometer.

Speed.—1,500 revs. per min.

It will be seen from Fig. 3 herewith, illustrating the turbine in section, that it consists of a number of wheels mounted on a shaft revolving inside a number of cells in the casing. The first wheel carries two rows of moving blades and this wheel is compounded for velocity. The following wheels have only one row of blades and the velocity of the steam by expanding through the diaphragm nozzles is completely used up on the moving wheel at each stage. The clearance over the tips of any of the blades is not less than 3/16 in., so that fouling or stripping is entirely obviated.

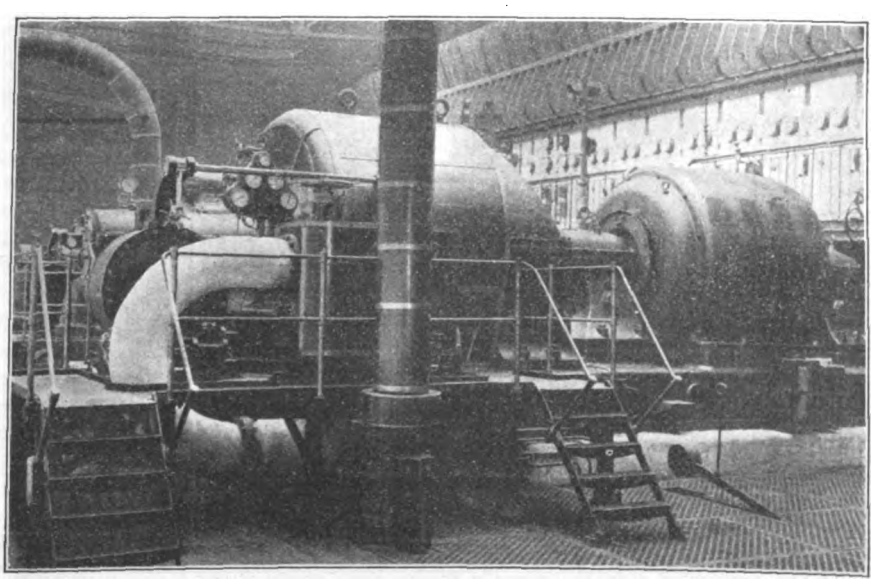

FIG. 2.—3,000 KW. TURBO-ALTERNATOR INSTALLED AT BRISTOL.

This type of turbine enables the use of very high steam pressures and temperatures without risk of injury to either

Digitized by Google

blading or casing, as only the nozzle boxes—which are two in number—are subjected to maximum pressure and temperature. The steam expands in the nozzles from 200 lb. per square inch (total temperature, 590°F.) to about 45 lb. per square inch gauge (the temperature being reduced to 350°F.) pressure, the superheat and pressure being converted into kinetic energy which is absorbed efficiently in the velocity wheel. The casing is thus subjected to comparatively low pressures and temperatures, so that no trouble is experienced due to distortion and expansion of the casing of the shaft.

The Westinghouse water glands are used at each end of the turbine and provide a perfectly air tight seal under all conditions of running. The complete machine as installed is shown in Fig. 2.

The official tests were carried out at Avonbank Electricity Works, Bristol, on March 18 and 19 by the British Westinghouse Co., in the presence of Mr. H. Faraday Proctor and other officials of the Bristol Corporation.

Steam consumption tests were taken at ½ load, ¾ load, full load, and 25 per cent. overload—each for a duration of one hour—all instruments used being calibrated immediately before and after the test.

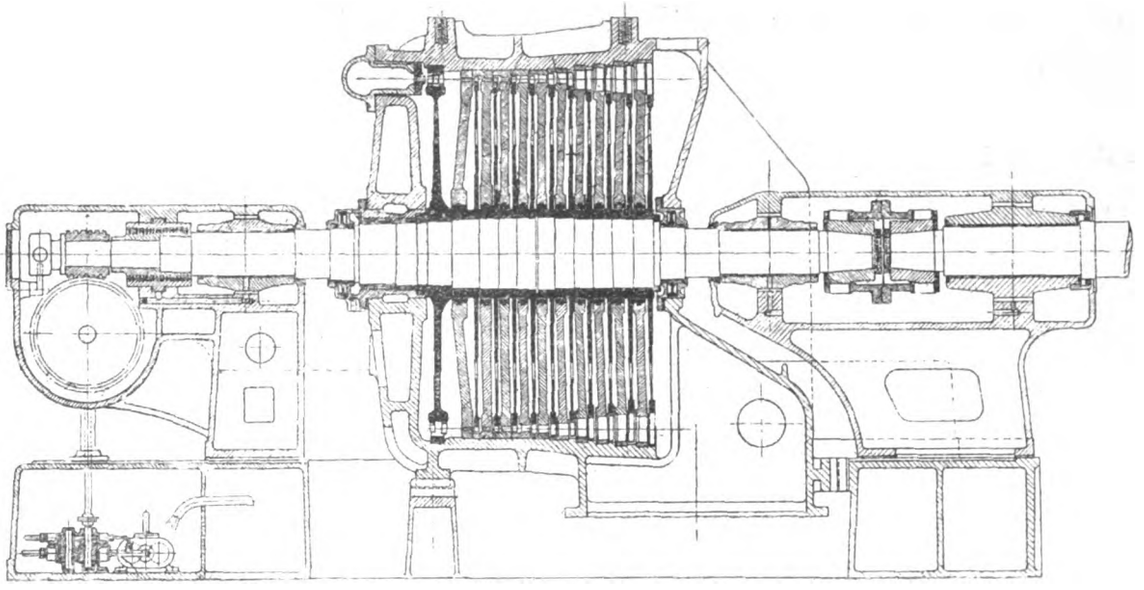

FIG. 3.—SECTION OF WESTINGHOUSE IMPULSE TURBINE.

In addition to the nozzles capable of carrying full load, separate nozzles are provided for 25 per cent. overload and full load non-condensing. Thus the consumption at 25 per cent. overload is even slightly better than at full load, since no steam is by-passed into a lower stage of the turbine.

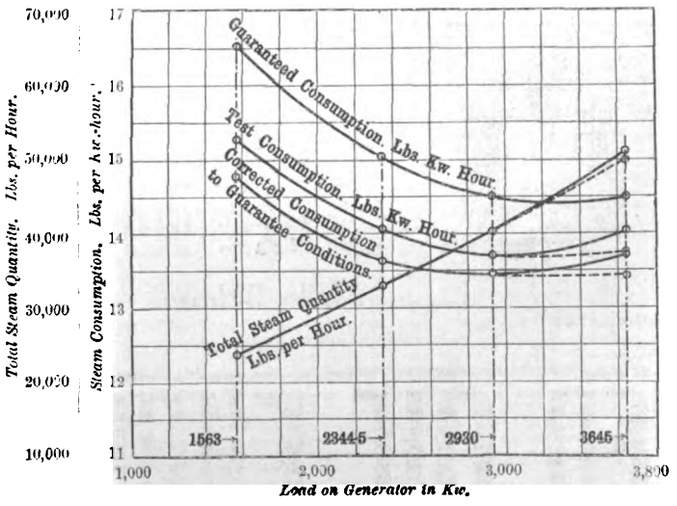

FIG. 4.—RESULTS OF TESTS ON A 3,000 KW. STEAM TURBO-ALTERNATOR AT BRISTOL.

The diaphragms splitting up the cylinder into a number of cells are provided on their outer periphery with guide blades, and in these the expansion of the steam is carried down to the condenser pressure. No expansion takes place in the moving blades, consequently there is no tendency for the steam to leak past the tips of the blades, and it is due to this that fine clearances are not necessary. The blades are cut out of the solid and secured by rivets to the periphery of the wheels. This arrangement of blading is clearly shown in Fig. 1.

Approximate Load.....	½	¾	Ffull	1¼
Output, kilowatts	1563·0 ...	2344·5 ...	2930·0 ...	3645·0
Speed, revs. per min.	1505·0 ...	1490·0 ...	1500·0 ...	1501·0
Steam pressures, lb. per sq. in.	192·5 ...	189·2 ...	195·4 ...	193·6
Steam temperature, deg. Fahr.	556·0 ...	560·0 ...	568·1 ...	565·0
Steam superheat, deg. Fahr.	171·2 ...	176·6 ...	182·1 ...	179·7
Vacuum (30 in. barometer) in.	28·42...	28·47 ...	28·18...	27·7
Circulating water inlet temp. deg. Fahr.	41 ...	41 ...	43 ...	41
Circulating water outlet, temp. deg. Fahr.	59 ...	61 ...	64 ...	66
Energy for air and circulating pumps, kilowatts	45 ...	46 ...	48 ...	46
Steam consumption. Total lb.	23,887 ...	33,015 ...	40,200 ...	51,171
Steam consumption, lb. per kilowatt-hour	15·28...	14·08...	13·72...	14·0
Ditto, corrected for 200 lb.... pressure 200°F. super-... heat. (Vacuum as during test)	14·78...	13·64...	13·47...	13·7

The corrections allowed for variations in the steam pressu and temperature as from the specified conditions are 1 per cen for 10 lb. pressure and 0·9 per cent. for 10°F. superheat. N corrections have been made for vacuum, as the contractor ha the benefit of more than 28 in. with barometer 30 in. Th curves in Fig. 4 show the results of the tests in diagrammati form.

Due to an error when the overload test was made, the by pass valve for running the turbine non-condensing was ope instead of the valve provided for 25 per cent. overload. Th dotted lines in the diagram show the results which would hav resulted under proper conditions.

We may also mention that the generator is separately excite from a 100-volt system, the energy required varying fro 276 amperes at 51 volts at half-load to 291 amperes at 55 vol at 25 per cent. overload.

We are indebted to Mr. H. Faraday Proctor, engineer a manager of the Bristol Corporation Eletcricity Departmen for the particulars of the tests given above.

CORRESPONDENCE.

WIRELESS TELEGRAPHY IN RELATION TO INTERFERENCES AND PERTURBATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—With reference to the letter by Messrs. Bellini and Tosi on the above subject in last week's issue, much more has been read into my remarks on triangular directive aerials than, in my opinion, is justified by the brief reference made to them in the Paper. Had I been concerned in expounding the capabilities, or summarising the pros and cons of directive aerials, I would have entered into the matter in much greater detail. Far from contending that the use of such directive aerials limits the range of signalling, I would at least say that it ought not.

In the Paper I have considered a particular case—viz., a suitable type of installation to afford communication between two fixed points separated by a relatively short distance. For such a purpose the triangular aerial (which involves the use of a single mast only) set in oscillation with its fundamental frequency has certain stated advantages. That is all. If into this statement the meaning is read that the system is unsuited for long distances, I must disavow any intention of conveying such an idea. It is, perhaps, a little unfortunate from Messrs. Bellini and Tosi's points of view that short distances were mentioned, but I am unable as yet to speak with authority as to the efficacy of the method over long distances in relation to its capabilities of eliminating disturbances of all kinds. I see no reason, however, why suitably arranged directive aerials should not retain their advantages, in this and other respects, over long distances.

It may be that in the reference made in my Paper I was not sufficiently explicit, but I feel that Messrs. Bellini and Tosi are "crying before they are hurt." I am sorry they should consider I am so little interested in the developments of wireless telegraphy as not to have read their more recent accounts of investigations, but it may reassure them somewhat to know that the only part of their letter which conveys anything new to me is the last paragraph.—I am, &c.,

G.P.O., London, April 22. J. E. TAYLOR.

CRUSE *v.* WILLANS & ROBINSON, LTD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Mention is made in your columns this week of this law-suit in which we as defendants have been unsuccessful. As enquiries have reached us regarding same, may we point out, to prevent misconception, that the action arose solely on account of work done as far back as 1906-1908 at the Company's Queensferry works, and is in no sense connected with the main works at Rugby.

The Queensferry works, it may be remembered, were built for the manufacture of boiler and kindred work, and were closed in 1908.—We are, &c.,

Victoria Works, Rugby, April 22. For Willans & Robinson, Ltd.
C. S. ESSEX, Secretary.

FOREIGN COMPARED WITH HOME INDUSTRIAL FINANCE.*

BY L. JOSEPH.

The author does not here deal with all the aspects of industrial development and industrial organisation, but confines himself to an enquiry into the financial problems relating to industries here and abroad in order to show to what degree the organisation of industries is dependent upon the supply and organisation of capital and credit.

For large enterprises the financier has always been a necessity, but since the introduction of machinery, power plants, and modern production on a large scale have revolutionised business and industry, has the financial element played such an important part in our economic system. It seems to me that the difference in the initiation and financial construction of industrial enterprise on the one hand, and the relations between industry and the financial element on the other, are largely responsible for the course which the development of industries has taken in different countries.

The relations between English industry and English banks are only of a very loose and superficial character; beyond keeping a regular cheque account and the occasional discounting of bills with the bank, there seems to be very little intercourse. Therefore, when an iron manufacturer, say, wishes to convert his business into a limited liability company, recourse is taken to the financial agent or promoter, to whom the business may be an unknown quantity, and when the prospectus is issued inviting subscriptions there is no indication that any financial firm standing sponsor to the company is making itself responsible legally or morally for the issue; the prospectus is not signed by anybody. The promotor then approaches certain financial circles in order to get the issue guaranteed by means of underwriting or otherwise at a commission. This being accomplished, an issue is made, a special settlement on the London Stock Exchange applied for and the official quotation obtained if possible. There the function of the promoter and his interest in the concern generally ceases, unless he has taken his profit in shares, which he usually wishes to turn into cash at the earliest opportunity. The brokers of the company, as a rule, are in the same way not further concerned about the subsequent market developments. Necessarily, also, the company starts with capital inflated as a result of the capitalisation of the goodwill and by the promoting expenses, &c.

Great Britain possesses enormous wealth, the savings of centuries derived from trade and industrial activities. Wealthy people usually invest part of their fortunes in industrial undertakings if they have originated from a family engaged in industry. The medium capitalist in England is disposed to put a substantial portion of his capital into industrial enterprises in which he takes an active part. In case he chooses to make temporary or speculative investment, he directs his attention to Government stocks, mining shares, &c., which have an active market on the London Stock Exchange. The small capitalist also selects this class of securities for his investments. Almost invariably securities of manufacturing concerns attract his attention only if he believes he knows everything or something about the business.

You will realise then that not only are the relations between banks, credit institutions and industry of an indifferent nature, but also, no doubt indirectly owing to these circumstances, the connection contact between industry and the stock markets are by no means close; at all events not so intimate as is desirable and as is the case in other industrial countries. There is hardly any occasion for English clearing banks to undertake transactions which may involve a shadow of risk. They invest their funds in discounting high-class bills, making advances on so-called floaters, gilt-edged stocks and on other securities at ample margin. Credit facilities in its wider application for financing trade and industry are, generally speaking, outside their sphere. Being able to earn dividends of up to or over 20 per cent. on their paid-up capital, they can afford to leave other departures alone. True, the branch offices of the clearing banks in industrial centres grant overdrafts in some measure, but they are not of great importance, and cannot be relied upon at all times. Depositors in England, by reason of traditional custom, more than by their own thought and conviction, take it for granted that credits to industrial enterprises, in the form and measure granted by banks on the Continent, for instance, involve undue risks, and, therefore, at any period of uneasiness, severe reaction or collapse in industry, they would naturally take alarm and withdraw their deposits momentarily. In surveying the influences inimical to industrial developments we have to take these circumstances into account, but I propose to show later that such notions do not prevail among Continental depositors; at all events, not to such a degree as here. As for the other banks—merchant bankers and credit institutions—they almost exclusively devote themselves to financing regular commercial transactions which are being liquidated within short periods, and are not generally concerned in industries.

In referring to the American industry one is in the first place impressed by the swift pace of development. One hundred years ago America had but little capital, and it was for this reason that industrial enterprises were established on the basis of associated capital in the company form. These were one and all more or less local enterprises for purely speculative ventures, such as mines, oil-springs, &c., the interest of wider circles even in Europe was always invited. Industrial stocks, though being quoted on provincial exchanges, have been, until recent years, excluded from the official listing on the New York Stock Exchange. Only since the formation of the larger trusts have the authorities of the Stock Exchange recognised the desirability to alter their attitude in according a welcome to this

* Paper read last Tuesday at a meeting of the National Business Men's Association.

Digitized by Google

class of securities, and American financiers have taken a keen interest in industrial developments for a considerable time past.

For some time back the reformation of the complicated banking system in America has been under careful consideration, but thus far without result. The different classes of banks, National banks, State banks and Trust companies, like the English banks, also administrate the available funds of the public. By the regulations of the Government they are strictly forbidden to engage in any speculative business and to grant credit facilities above one-tenth of their own capital to one and the same party. Only the National banks, about 7,000 in number, enjoy the privilege of issuing notes, whilst the establishment of branch offices is prohibited to all of them. This explains the large number of banks all over the country, most of which have only a very small capital. The capital of individual banks being very insignificant, industrial enterprises are bound to have access to the resources of a number of banks and credit institutions.

Commercial transactions in the States are based on three or six months' credit or even for longer periods. It has, therefore become customary for commercial and industrial concerns to issue and discount their own promissory notes through so-called note brokers in the market (who, however, do not take any responsibility in the way of endorsement), or direct with the banks all over the country. This single-hand paper in America forms the basis of the currency for the note issue of the National banks. You quite see the danger of that system in the event of the banks simply withdrawing or curtailing their investments in promissory notes with a view to increasing their cash resources in times of uneasiness or crisis. Nevertheless, this is the usual way in which American trade and industry, even very large firms, finance themselves.

American industry is still in need of large amounts of capital. The big companies and trusts are in a better position to raise the necessary funds than smaller concerns, whether in the form of credit or by the issue of capital. The banking community, in co-operation with capitalists, who partly have themselves made their huge fortunes in industry, take an active interest in promoting industrial developments and flotations, whilst the confidence of the general public in these gigantic organisations is obviously increasing with their successes. The result is that the progress of amalgamating, combining and establishing community of interests will continue, unless action is taken to enforce the act which is directed against the trusts. Whatever the outcome of the important decisions expected daily the principles underlying the industrial development and the close relations now prevailing between finance and industry cannot become seriously affected.

Much tighter than in England and *much more* interwoven than in America are the relations between industry and banks and credit institutions in Continental countries as Germany, Switzerland and Austria, except, perhaps, France. The termination of the war of 1871 and the inflow of the war indemnity gave a great stimulus to German enterprise. A number of new banks, classified as "Credit Mobilier," were established, largely in the provinces; and a concession was granted for the erection of the Deutsche Bank, in Berlin, with a capital of £750,000. However, the spirit of enterprise soon transgressed the limits of solid developments, and a severe reaction set in, resulting in 1873 in a crisis, the result of which was that not less than 73 banks, with a capital of 21¼ millions sterling, were forced to liquidation within the following six years. In 1875 the Imperial Reichsbank, succeeding the Prussian Bank, a Government institution, was founded. The Reichsbank is also under the control of the Government, though its capital is privately held. It has the privilege of note issue, and its constitution and functions are, upon the whole, identical with those of the Bank of England; with the distinction, however, that its power of issuing notes is elastic to a certain degree, whilst its regulations in respect to discounting bills are not so discretionary. The Riechsbank is managed by the President, in conjunction with a committee, the members of which are appointed for life, and controlled by a board of five members, the president of which is the Imperial Chancellor. The development of the Reichsbank, its able policy and operations, its co-operation with the credit banks, have undoubtedly exercised a beneficial influence upon the whole industrial and banking system in Germany.

You must bear in mind that in Germany and on the Continent generally, it is a recognised privilege of the banks, it is their *raison d'être*, to cultivate all branches of banking transactions. German wealth has not yet assumed such proportions—at any rate the loanable capital has not yet increased to such an extent—as to encourage the establishment of deposit banks pure and simple. Besides, neither the German capitalists nor the small saving classes are used to leave their money on deposit for any length of time; they are much more eager to invest it in securities. Moreover, in view of the recognised activities of banks, the public at large does not find anything disquieting or unsafe in the manner in which banks seek employment for funds entrusted to them. Confidence in the administration of the bank has, in the course of years, been so fortified, that only a serious catastrophe could seriously shake it. Can such a calamity happen? It seems almost impossible, considering the enormous amount of share capital and reserves of the big banks, of the solidarity of interests amongst them, the efficient control exercised by the board of directors, and the influence and assistance of the Reichsbank in the last resort.

The process of concentration that has been going on for years in Germany, and is still going on, and the growing responsibility of the enlarged boards of directors, make no doubt for still greater circumspection and care in the future without necessarily affecting the policy of encouraging industrial development.

Although the industrial activity which set in after 1871 was overdone, it received an intense and lasting stimulus by the nationalisation of the railways. The leading financial circles commenced immediately to direct the flow of capital towards industrial enterprises of all descriptions, especially ironworks, collieries, machinery manufacturers, engineering and electrical establishments, &c., by way of promoting and floating companies, &c. Meanwhile the company law has been greatly reformed and improved, protecting the public in every possible way from being deceived or misled by misstatements in the prospectus in respect of goodwill or otherwise. Under all circumstances two annual balance-sheets of the company after its registration have to be submitted before the securities can be introduced in the market. Most stringent regulations as to the responsibility of directors have been formulated. The prospectuses have to be signed by the issuing firms, who thereby make themselves responsible for the correctness of statements, and at the same time place their prestige and credit as issuing houses at stake. A committee of able bankers and merchants appointed by the Government, after most careful and searching investigation into the facts and figures in the prospectus, being authorised to demand any necessary explanations, has to express its opinion as to the desirability of allowing the security in question to be introduced and quoted on the Stock Exchange. All these precautions are most beneficial in creating an atmosphere of confidence and trust for industrial stocks, the more so as the banks themselves are invariably represented on the board of directors, exercising considerable influence in the management of affairs, not only in its financial but also in its general aspects. The experience of bankers being connected with a vast number of different concerns, and gaining inside knowledge of different industries, is often very valuable, even in technical matters, in questions of amalgamations, combinations, cartels, &c.

It is, I believe, safe to contend that the constant shifting and changing, adding and adopting in the industrial development is due as much to the banking influence as to the leaders of industry themselves. Being so conversant with all the affairs of industries, and keeping in constant intimate touch, it is quite logical that the banks are ever ready to assist industries even in times of stress. They make advances to them for extensions, for new equipment, for acquiring discreetly, if necessary, competing works, &c. These transactions, which naturally in themselves are profitable to them, will finally result in further issues of capital and placing and marketing of shares, &c., by which they again secure fresh revenues. They do not, and cannot, consider their function at an end with the issue of the capital; they recommend the security to their own clientèle, and they regulate the market if there is need. Important transactions in industrial securities take place on the Berlin and other German Bourses daily. The public knows that not only are these investments of intrinsic merit, but also that they can easily dispose of them, even in times of great reaction.

Under the banking influence it has become more and more the policy of industrial companies to build up such reserves as to be able to avoid too sharp fluctuations in the dividend distributions. The balance-sheets of some companies give unmistakable evidence. I have got here the figures of Siemens & Halske, showing that since 1901 the capital has been increased from £2,700,000 to £3,150,000; the open reserve from £460,000 to £740,000; permanent investments, £560,000 to £3,200,000; buildings are unchanged at £500,000; tools, machinery, lighting plant, &c., are written down from £480,000 to 1s.; raw material is reduced from £300,000 to £100,000; manufactured and half-manufactured goods from £1,200,000 to £450,000; power station from £160,000 to £40,000; interests in other enterprises from £250,000 to £35,000. These figures tell a great tale. The permanent investments alone, as a result of the arrangement with Schuckert & Co., exceed the whole share capital. On the other hand, buildings stand at the same amount, regardless of the enormous extension of the works; tools, machinery, lighting plant, &c., have been written down to the extent of £480,000; stocks of raw material are valued at one-third of their book price of nine years ago; manufactured and half-manufactured

Digitized by Google

goods are £700,000 less, in spite of the great increase in the business. Anybody that can read a balance-sheet will recognise the enormous reserves which are hidden in these figures. The dividends since 1901 have been as follows: 8, 4, 5, 7, 9, 10, twice 11, twice 12 per cent.

Much more imposing still are the figures of the General Electric Co., that remarkable institution founded in 1833 as an offshoot of Siemens & Halske, with a capital of £250,000, which has since gradually risen to £5,500,000 with probably not much less reserves. Machinery, tools, models and patents of each single factory controlled by the company have been written down to 1s. The last balance-sheet, when the capital was still £5,000,000, shows credit balances at banks amounting to £2,200,000. Needless to say that this institution is not in any more dependent on banking credit, nor would it find great difficulties in placing its securities without the assistance of bankers. The intimate relations between the banks and the A.E.G., however, still exist: representatives of all the leading banks are on its board, evidently because their co-operation is of direct and indirect benefit and not because they are representing large shareholders.

It is generally acknowledged that the progress made in the electric industries in Germany has been most striking. Without disregarding the other factors conducive to this remarkable development, it seems to me that it was in large measure due to the intelligent and most liberal assistance by the financial circles that have quickly grasped the importance of this new industry. They have enabled electrical undertakings to secure work in both hemispheres by financing them through all the different stages; they were instrumental in affiliating to the electric companies their own financial houses and holding companies, and they have distributed the securities of all their enterprises, debentures and shares into the investing public. Without such faithful and powerful support, the electrical industries would never have forged ahead with such speed and gained the commanding position which they hold.

In conclusion, I believe to have shown that industrial credit does not necessarily involve banks in undue risks; that the organisation of Continental banks, which are essentially credit institutions, are efficiently equipped *both* financially and intellectually to cope with industrial requirements; that the co-operation between banks and financial institutions and industries *has* proved upon the whole advantageous to both; that the assistance of well organised stock markets is needed for placing and popularising industrial stocks as investments. It seems to me that for practical purposes it is more useful to give attention to these points than to fiscal problems which have been under discussion for a considerable time.

DISCUSSION.

Mr. Theodore Rich said we were inclined to be insular and to think our institutions were better than those of other people. Notes in the press frequently stated that we had lost business from lack of genius and energy. Was it not rather due to lack of facilities to use our enterprise to best advantage? Many would agree that it was to lack of the financial facilities that we owed much of the trouble in the electrical industry to-day. Our industry was more allied to that of Germany than that of America. Germany, like this country, was not able to use capital as it had. The question which naturally arose was "Could existing banking institutions take on industrial business?" We examined the bankers. They had grown up with the existing conditions. The banker was nothing but a bill broker in this country. He said, "We have the money market of the world, and there cannot be anything very wrong," and his business was so organised that it was impossible for him to touch anything in the nature of a lock-up of capital. The German banker traded largely on his own capital, and the English banker on that of his depositors, not of his own shareholders. The result was that he could not do anything which tended to lock up his capital. The English banker would lend money for many things which one could not understand why for here, and he wanted to see his money was properly secured. The English banker said, "Look at the record of the last 30 years. We have had practically no smashes." But millions of pounds were lost in industrial promotions because there were no responsible bankers to look after them. One thing that could be laid at the door of the banks was the appalling waste of industrial capital that had gone on for many years. The German banker took an interest in the industrial concerns of his country. The leading financiers of London had practically no interest in British industrial undertakings, and many of them had large interests in the industries of other countries. We wanted a system by which industrial capital was more spread amongst the people and not entirely in the hands of individuals. Everybody would then be interested to push the industries. The company promoter had no chance. The banking interests took no heed of the matter. In Germany the big financial concerns kept the money in the right lines so as to benefit the country. We could not shut our eyes to the fact that it was a matter of national economics. Germany said it was the duty of every man to do something for his country, and if our financial interests were more in accordance with industry we should get on better than we did.

Mr. W. S. Mann said the function of bankers here seemed to be to have a knowledge of the distinction between a mortgage and a bill. It was the nature of the security they looked at so much as its realisability. That was due to the nature of the business in which they were employed. Some sort of organised authority was almost a necessity for us under present circumstances. Germany, and the large institutions in the electrical industry particularly, had the advantage not only of organised capital in a superlative degree, but of organised experts. Germany was the largest competitor of England not only in South America, where the field for electrical energy was being rapidly filled up, but in our own colonies. The Victoria Falls Power Co. was an undertaking known to a large number of people in England, but it was found difficult to raise the capital here, and while the British financial houses were considering the matter the Germans had been approached and had made a proposition that if they had all the orders for the machinery and other privileges they would pay £100 of debenture money to every £100 of preference money behind those debentures. The result was they had found three millions sterling in debentures and England had three millions in preference shares behind those debentures. The Germans had also received orders amounting to six millions sterling, and would receive orders for another two or three millions. If we had had some organised industrial bank which had given the capitalist in London the assurance which the A.E.G. gave to the German capitalists none of that money would have gone out of English hands. Directly the German institutions and experts set their hall-mark upon the enterprise the English capitalists came forward and said it was good enough for them. He could give similar instances in South America.

Mr. G. H. J. Hooghwinkel said he was in complete agreement with the last two speakers. There were many similar examples in South and Central America and the Far East. While we were negotiating for 10 years' options, &c., the German power of attorney was on the spot and clinched the matter, as a rule at a lower price than we could have offered. The ideal course of altering our system, which he supposed occurred to nearly everybody there, would be to establish an industrial bank similar to three or four which existed in Germany. There had been a lot of talk about this during the last two or three years, but they had not got much further. He suggested that the Association should take up the question officially, and have a meeting to discuss a resolution in favour of the formation of a committee to consult with some bankers. He did not suggest the Bankers' Institution, which was too high above them, but some selected bankers.

Mr. Hugo Hirst dwelt on the question whether the introduction of influential people to an industrial concern was more possible under the German than under the English system. We could get money by the means the author so ably described—by prospectuses—but the shareholders had no interest in the business; they only desired dividends, while the "industrial" who had got the assistance of the capital was really in a dangerous position. The latter knew nothing of finance. When he got more than enough money for his requirements his troubles commenced. He either got careless or schemed how to invest his surplus capital, and for the latter purpose he wanted just that advice which the German banks and financiers gave, which the English private banker gave the "industrials" in the olden days, and which they were unable to obtain under the present system. It was announced in the Press recently that Germany had decided to send technical men as attachés to its Embassies abroad, and it was suggested that England should do the same. But what could a technical expert do in our Embassies. He might report to the Board of Trade, who might send notices regarding the matter to a few private people, who would all be turned at once into applicants to the bankers; but for the big schemes now looming ahead in foreign countries great technical, financial and commercial power was wanted, and they could not be dealt with by individual firms even backed up by money, if they were not backed up by experience such as foreign competitors had at their disposal.

Mr. H. Oppenheimer said the result of the negotiations with regard to the Victoria Falls Power scheme was the general outcome of the natural disposition prevailing in this country—slow and sure—and that absolute surety, so far as the bank's business was concerned, had its advantage. A crisis would not affect an English bank, and whether that was certain to be the case on the Continent it was not for him to discuss. It had been said by the previous speakers that our ill-success from an industrial point of view resulted from lack of machinery for getting capital. The cotton industry, cited by Mr. Joseph, was not created by the joint stock banks, but by the support of the private banker, and the same thing had happened in Germany. It was a mistake to think that the industrial progress there took its rise from the large banking institutions. The German bankers took a leaf out of the Lancashire private bankers' book, and nursed the local industry where there was some industry. With the rise and progress, financially, of Germany, it was easy for the gentlemen at the head of the banking business to pick up the growths that had been nursed and matured, and they were now supported by unlimited capital. The private banker was the first to support local industries, and the same would be the case to-day if our banking institutions were not exclusively controlled by a large trust of joint stock brokers. An ordinary "industrial" going to his bank and desiring to discount a bill would not get it discounted unless his balance was sufficiently large. The gentlemen controlling the large financial interests were ready to advance unlimited sums to gentlemen connected with the Stock Exchange who required daily accommodation, but when an industrial concern, ever so sound, appeared on the scene the coffers were locked.

Mr. Donovan said the author was wrong in stating that the change came about through the introduction of machinery. It commenced by the Bank Charter Act of 1844, when gold was made the legal standard for payment of debts, &c. It gradually shut out the private banks and prevented them issuing paper money. Agricultural industry declined from the passing of that Act.

Digitized by Google

Mr. W. L. MADGEN said he felt there was still something good in our institutions and in our methods. The only statement of fact from which he was inclined to differ was the method of formation of what the author appeared to regard as a typical company in this country. He did not think it a fair description. There was a large number of companies which were very well managed and very successful. The author had not referred to the large number of financial houses, wealthy and responsible firms, in all our large centres who devoted themselves to the support and control of different classes of business, and who fulfilled all the functions of the German banks, and he thought more efficiently than the latter. It appeared to him that the German and American banks did not exist so much for the industries as the industries existed for the banks.

The CHAIRMAN (Mr. H. W. Butler) said the English banks did not seem so much to blame. While they could return their shareholders 20 per cent. dividends they could well be content and consider they were doing good business. This being so it was no good trying to reform those banks. The speaker who suggested industrial banks for the special purposes of industrial enterprises appeared to him to have hit the nail on the head. He took it the enterprise of the German banks was chiefly due to the fact that they had not ready means of turning over their capital sufficiently often to produce the necessary dividends.

The AUTHOR said, in reply to the discussion, with regard to the creation of industrial banks, it was of no use to go on with any such project before an atmosphere of confidence in industrial enterprises could be created, and this could only be done by safeguarding the promotions and management of the affairs of the undertakings. In spite of the modifications that had been made in the Company law, there were still many methods of getting around it. Companies and shares of companies were introduced on the London Stock Exchange with no prospectus and no responsibility, and the bigger the profit made out of the promotion the bigger were the ultimate losses. So long as such methods prevailed he was afraid no industrial bank would be sufficiently attractive for capitalists to put their money into. The first alteration should be by the Government safeguarding the capital of the public. He had not said the change of the banking methods was caused by the introduction of machinery, but that the whole economic structure was changed at that time. The change in the banking methods was the result of the wealth of the English nation. With regard to Mr. Madgen's remarks, if it could be shown that the German industries had suffered by being intimately connected with the banks or the banks through intimacy with the industries, Mr. Madgen would be right. The object of his Paper was to find means of enabling English industrial concerns to alter as the German industries had done. The banks were not to blame for having made large profits. They had given their time, intelligence and capital to the industries, and they should have the benefit.

IMPERIAL TELEGRAPHS.

At a meeting of the Royal Colonial Institute at the Hotel Metropole, London, on Tuesday, Mr. Charles Bright, F.R.S.E., read a Paper on this subject.

Sir FREDK. YOUNG occupied the chair, and referred to the practical engineering attainments of Mr. Bright, the services he had rendered to telegraphy, and the various expeditions he had been engaged in. He supported Mr. Bright's view that cheap cable communication of an Imperial character should be provided.

In his Paper Mr. BRIGHT said: The forthcoming Imperial Conference serves to revive in many people's minds the need for more direct and less costly telegraphic communication between the different sections of the British Empire. That we are already provided with a highly efficient—if expensive—international cable service no one can reasonably deny. There is, however, a growing feeling that the Mother Country and her oversea dominions should be in closer and more easy commune with one another—partly with a view to increasing the scope of inter-Imperial trade. So far, however, they had not really got much beyond the idea. He would ask his hearers to recognise that just as, in order to ensure peace, we must—in the matter of armaments—be abundantly prepared for war, so equally it was essential that we should be telegraphically equipped in such a way that we can at all times rely upon talking freely, yet secretly, with the rest of the Empire.

For our cable service we are mainly indebted to private enterprise. Less than a sixth of the total of our submarine cables belong to the Governments. This is, however, a distinctly rising proportion, for foreign Governments are adopting a policy of State-owned and State-administered cables to their outlying possessions. A fair number of the cables laid by private companies have been entirely provided for by capital raised by themselves. On the other hand, large subsidies have been obtained from the Home and Colonial Governments for several important lines to the British Dominions. It would seem on the face of it that where private companies sought, and availed themselves of, subsidies from the State, they could not rightly object to either Government supervision or Government competition, or, alternatively, the subsidising of some rival enterprise, such as they had not been willing to undertake themselves on satisfactory terms.

It seemed to him that a great advance would be made in inter-Imperial communications if an all-round Imperial cable tariff—say, of 1s., 9d., or even 6d.—could be put into operation. The actual figure might be made a subject for investigation by a Government enquiry. There were, doubtless, difficulties in realising a uniform Imperial rate, but really useful work would be accomplished by any Government that took steps towards its realisation. The companies are, in the main, in a very strong financial position. Their reserve funds are largely based on what was once the accredited life of a cable—20 years—rather than double that period, such as is now known to be nearer the mark. In these circumstances, he imagined they would be prepared to meet Government suggestions in the matter if negotiations were pursued on right lines and in a suitable spirit. Some of the comparisons that had been made with railway traffics were altogether beside the mark; though, on the other hand, there appeared to be quite as strong reasons for Imperial cable tariffs being regulated by the State as for the 1d. a mile Parliamentary fare in force on the railways. He realised, of course, that the companies had reduced their rates considerably from time to time without incurring the disastrous results that had sometimes been feared. It had, however, always been admitted that if the Government took over our Imperial cables the rates could be substantially reduced.*

While increased overhead charges and additional cables constituted a real objection to tariff reductions, even with companies possessed of immense reserve funds, this difficulty had of late been met to a great extent by a recent invention—the cable relay—which permitted of a cheaper type of cable for a given volume of traffic, and, correspondingly, by its adoption at intervening points the same type of cable had a greater earning capacity. Hitherto, when once long continuous spans of cable had been satisfactorily dealt with, the elimination of intermediate stations—unless of a remunerative nature—was always aimed at, in order to dispense with manual re-transmission. Now, however, this re-transmission being effected far more efficiently and economically by machinery, it is usually considered good policy to take the line to as many intermediate points as are reasonably on the route.

The question of reduced rates for messages to be held back for any time up to 24 hours has been once more under "close observation." The cable companies, perhaps naturally, cater almost exclusively for business messages, which form at present 96 per cent. of the whole. In this way 17 Atlantic cables are kept well employed during the four or five business hours in common on each side of the ocean. By the introduction of lower rates for deferred messages the remaining hours could be turned to more profitable account by the cable, in the same way that certain railway companies fill their trains with ladies in the middle of the day. It is understood that the Eastern and its Associated Companies were now favourable to the reform, though they were certainly not so when he, for one, advocated it before the Cable Communications Committee in 1900.†

The present Postmaster-General (Mr. Samuel) appeared to favour the deferred-rate proposal, recognising that "too heavy a burden falls on individuals desiring to send messages by cable." An official conference was still considering this subject at intervals. Various suggestions had been made as to the exact form the deferred-rate system should take, and no definite decision had yet been arrived at. The most generally approved form appeared to be on a plain English non-code basis, the message being sent within 24 hours, the tariff charged being half that by ordinary rate. Both the German and French Governments were in favour of this reform being universally adopted, but the reform was still deferred. If the cables at present serving the Colonies were left in the hands of private enterprise, either fresh cables must be laid for the purposes of a cheaper new service or Government should endeavour to secure a more favourable tariff.

The strategic aspect of the cables was a more important feature than any other they had to consider. The necessity of being in constant communication with our outlying tributaries could scarcely be over estimated. An agreement had recently been entered into between the French and German Governments, the object of which was to render those countries independent of British cables—more especially for communication with Africa. The agreement provided for the common use of their respective submarine telegraph lines at any time that "accidents of a technical or other nature" interfered with the normal working of the individual services. But perhaps the most striking feature of this agreement was the laying of a Franco-German State cable between Brest and Emden with German extensions to Monrovia (West Coast of Africa) and Pernambuco (South America). If telegraphic communication with our colonies were needed only for individual purposes, there would, he considered, be no justification for the Government embarking on the expenditure of public money for State-owned cables. But such communication was highly necessary for the nation—(1) strategically, (2) politically and (3) for developing inter-Imperial trade. While there were objections to State-trading, there were more sound reasons in favour of Government-owned strategic cables to our distant possessions than would apply in the instance of State railways or the Government land telegraph system.

He trusted he had set forth sufficient grounds for a liberal expenditure in State-owned or State-subsidised and controlled cables to the various points in the Empire on a variety of routes, so that where one cable was

* Sir James Anderson (the late distinguished managing director of the Eastern and Associated Telegraph Companies) once remarked that if Government in taking over the telegraphs (meaning apparently the British cable system) could reduce the tariff one-half and still make a profit. "Private companies," he added, "could not do that." ("Proc. Roy. Col. Inst., Vol. XIX., p. 212).

† On that occasion the companies proposed as a substitute that three rates should be adopted for "preferential" messages marked "urgent" which were to be given priority. In other words, no reduction on the ordinary messages was agreed to under any pretext, but instead an increased tariff was suggested for messages of an extra-urgent character. His suggestion was made mainly with a view to developing priority messages, but also for obviating the necessity of coding and de-coding in the case of many business cablegrams of a non-urgent character.

DISCUSSION.

H. E. Rawson, R.E.C.B., approved the author's contention that ... Government should make certain conditions when granting landing ... for cables, and especially when it came to another Power taking ... over. He thought an Imperial Board should be appointed to ... the subject.

Sir Thos. Troubridge said the Atlantic cables seemed to be on the ... of coming into the hands of our friends the Americans, and cir... might arise in which they would have to be neutral—say, in ... war. As the Government were to subsidise a line of steamers to communicate between Great Britain and her colonies through Canada, perhaps they would subsidise a cable also.

Capt. Thomson, C.B., expressed surprise that so many more cables had been laid since he was engaged in cable laying some years ago. He thought it was a question whether wireless was not likely to supersede cables.

Mr. G. R. Neilson said Mr. Bright had referred to a uniform rate throughout the Empire. That would be very desirable, but one had to see that one did not get below the prime cost of the article which was to be provided. Communication with the other side of the world must be an expensive matter. The net cost of a message would be considerably more than one shilling. With regard to the cable relay cheapening the cost of telegraphing, it did so to some extent, but not to any very marked extent compared with the cost of the cable and its depreciation. The relay had been working for some time, and had undoubtedly afforded a benefit in rapidity of transmission. The uniform rate for inland telegrams in this country had resulted in a considerable annual loss. If traffics were greatly increased by reduced rates the number of cables would have to be increased. These had a certain carrying capacity, and if the messages to pass through these cables could be spread over the whole of the 24 hours there would be a considerable margin; but messages, for a variety of reasons, had to be forwarded (and possibly answered) in a short time. The concurrent working time between England and New York was only about three hours daily. The cables would require to have a very much larger carrying capacity than now if the traffic was to grow to any great extent. He thought the idea that wireless was on the eve of taking the place of cables was a little previous. Hitherto wireless had played the part rather of a feeder than that of a foe to the cables. The greatest desire of the Government was for the security of communication; that took first place, and was far beyond cheapness. Obviously it was for the interest of this country to encourage cables. Wherever they might be laid some benefit almost always accrued to the British Empire. At all events, the cables provided so many alternatives that it would be hardly worth the while of foreign Governments to cut some of them. If the Atlantic cable were cut, we should not be cut off from our colonies, as we could go another way round. He did not imagine that the Atlantic cables would pass into the hands of the American Government. He thought they would remain in the possession of the British companies. He did not think Mr. Bright allowed sufficiently for the danger of ice, and especially icebergs, in the northern regions, and he certainly did not think any responsible engineer would lay a cable up the St. Lawrence, for during a considerable part of the year it would be impossible to repair it. The carrying out of Mr. Bright's large views would involve the expenditure of a sum which perhaps even a wealthy country like ours might not care to face.

Mr. Bright, in reply to the discussion, said he thought that when Sir Thos. Troubridge mentioned the serious position which might be created in the event of an American combine obtaining possession of the cables he was forgetting for the moment that we had the eastern route to Australia. He felt sure Sir Thomas was correct when he said ice was no difficulty at Halifax, but he felt, with Mr. Neilson, that it was a difficulty which must always be borne in mind in the St. Lawrence. He also agreed, more or less, with Mr. Neilson with regard to wireless telegraphy, but we did not know what science had in store for us. He did not know whether Mr. Neilson went so far as to say that wireless telegraphy would never take the place of cables. He (Mr. Bright) would be sorry to say that. They knew at present that wireless was a very different thing from cable telegraphy, and he would be sorry to rely upon it entirely. He thought they required both systems. With regard to a uniform rate, he quoted what Sir James Anderson had said: "That the Government, in taking over the telegraphs, could reduce the tariff by one-half and still make a profit," and, further, that "public companies could not do that." Mr. Neilson said he (Mr. Bright) was quite wrong about cable relays.

Mr. Neilson: I did not say you were wrong. I said it was already in use and we had derived benefit from it.

Mr. Bright: I know people who are authorities on the subject who agree with my views as to what can be done on an Atlantic cable with cable relays. Continuing, he said they could either use a cheaper cable on account of the cable relay, or send a greater number of messages with the use of the relay on the existing type of cable. The daily common period for working between England and America was four or five hours. It was a matter of degree. Five hours were in common use and three hours were more general. Sir Samuel Griffin, a former Premier of Queensland, had said that, prior to the laying of the Government's Pacific cable, Australia's means of communication was a source of anxiety, because the Eastern and Eastern Extension Companies' cables ran through foreign countries and through seas which were full of the ships of foreign countries. Mr. Neilson had credited him (Mr. Bright) with large views, and he would remind him that the splendid work done by the cable companies would not have been effected but for their large views.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Bright for his paper.

Electricity in Mines.—At the conference of the Miners' Federation on Wednesday the Mines Bill was further considered, and it was decided unanimously to refer the whole question of the use of electricity in mines to the Executive Committee, with a request to draft an amending clause to be submitted to a subsequent conference, so as to increase the safeguards in the bill as to the use of electricity.

*As a matter of fact, no other course is open; for, just as no foreign ... would grant landing rights for a *British Government* cable on ... so, similarly, the moment a private-owned cable was taken ... Government the landing rights would be abrogated.

PARLIAMENTARY INTELLIGENCE.

HALIFAX CORPORATION BILL.

This bill came before the Local Legislation Committee of the House of Commons on Monday, Sir W. E. B. Priestley presiding. The bill authorised the construction of additional tramways, &c.

Mr. TALBOT, K.C., for the Corporation, said the tramway system now consisted of 37 route miles, and the traffic was heavy and increasing. The list of proposed tramways appeared formidable, but they were very largely proposals for doubling existing lines. One of the portions of the route to be doubled was Waterhouse-street, and to this there was opposition.

Mr. W. M. ROGERSON, borough electrical engineer, gave detailed evidence as to the desirability of the improvements.

After hearing Mr. Rogerson, and his cross-examination on behalf of the objectors (by Mr. Charteris), the CHAIRMAN said the Committee were unanimously against the doubling of the line in Waterhouse-street.

Counsel for the promoters, however, begged the Committee to hear the evidence of the Borough Engineer before coming to a definite decision, and the Committee consented.

Mr. C. F. SPENCER, chairman of the Tramway Committee, said they had paid great attention to the proposals to set right their system on which there had, owing to an accident, been a loss of £12,000. The only part of the system which was not a commercial success was the Waterhouse-street section. After four years' consideration they decided that their present proposal was the only practical one.

Mr. S. SELLON, who has called in to advise the Corporation, considered it absolutely essential to the successful working of the undertaking that that particular section should be doubled.

Mr. JAMES LORD, borough engineer, quoted instances at Halifax, where there were roads equally narrow where they had double lines already without any interference with ordinary traffic.

The Committee then decided that they would permit the double lines for one portion of the route suggested, but not through Waterhouse-street itself.

The Standing Orders Committee have authorised the insertion of a clause permitting the construction of a new tramway along Park-street, in place of the existing line in Northgate and North Bridge-street.

Mechanical Appliances on Railways.—In reply to a question, the President of the Board of Trade (Mr. S. Buxton) said, in the House of Commons on the 20th inst., he had asked the railway companies to consider the desirability of providing mechanical or electrical appliances at places where detentions were frequent, or where trains were liable to stand out of sight of the signal cabin.

Brighton and District Tramways Bill.—The promoters have decided to withdraw this bill.

Greater London Railway Bill.—This bill will come before a Select Committee of the House of Commons on May 4, unless the Government accede to a request which will be made to refer it to a Joint Committee.

Macclesfield & District Railless Traction & Electricity Supply Bill.—Application is to be made for leave to introduce in this bill provisions to enable the company proposed to be incorporated to acquire lands, erect and equip generating station and work trolley vehicles on an additional route.

Pontefract Provisional Order.—The Standing Orders Committee of the House of Commons have declined to allow Pontefract Corporation to introduce a bill confirming an agreement for the transfer of their Provisional Electric Lighting Order, 1907, to Yorkshire (West Riding) Electric Tramways Co.

Norwegian Telegraph Service.—In the House of Commons on Wednesday the Postmaster-General, Mr. H. Samuel, stated, in reply to a question, that the telegraph service between the United Kingdom and Norway had been acquired by the Government from the Great Northern Telegraph Co. Under the agreement between the two countries, the working of the cables would be entrusted to the Great Northern Telegraph Co., in whose hands the Scandinavian service still remained.

LEGAL INTELLIGENCE.

Tramway Bye-Laws.

On Tuesday a Divisional Court (the Lord Chief Justice and Justices Pickford and Lush) heard an appeal in the case of Smith *v.* Woodhead, from a decision of the stipendiary magistrate of Leeds. From the special case stated for the opinion of the High Court it appeared that on Sept. 15, 1910, an information was laid against Mr. Woodhead charging him with having, on Sept. 7, while a passenger on a tramcar in Leeds, unlawfully refused to show his ticket to Bentley Smith, an inspector in the Corporation's employ. Appellant had paid his fare (2d.), and had been offered two 1d. tickets by the conductor, which he refused to accept. The tickets were, however, placed upon the seat beside him. The inspector subsequently entered the car and requested to see appellant's ticket. The two tickets which had been placed upon the seat had fallen to the floor, but appellant made no reference to them, stating that he had no ticket. The inspector demanded the fare which could be legally demanded from a passenger who refused to show his ticket, but appellant refused to pay it. After hearing the facts the magistrate convicted Mr. Woodhead, fining him 5s., without costs, over-ruling an objection that the bye-law which said that a passenger who had paid his fare should be required to show his ticket was ultra vires and unreasonable.

After hearing counsel for appellant, and without calling upon counsel for respondent, the Court dismissed the appeal. The LORD CHIEF JUSTICE, who delivered judgment, said that before convicting Mr. Woodhead for not showing his ticket, the magistrate came to the conclusion that the passenger knew where the ticket was, and could have produced it had he liked. In these circumstances the Court thought that the magistrate was right in his decision, and the conviction would be affirmed.

Evans v. General Electric Co.

A Divisional Court (the Lord Chief Justice, Mr. Justice Pickford and Mr. Justice Lush) had before them yesterday (Thursday) this special case, stated by the magistrates of Aston. At the Petty Sessions at Aston on Nov. 23, 1910, an information was preferred by Wm. Evans, an official of the Midland Railway Co., against the General Electric Co., charging them with having attempted to evade the payment of certain tolls to the company, by describing 10 electric stators, consigned in two parts, as "two cases bearers."

Defendants obtained a contract to supply to Bedford Corporation certain electrical machinery, including an alternator. This was consigned from Witton to Bedford via the Lawley-street station of the Midland Railway. A portion of the goods was an electric stator with laminations and coils, which was placed in two cases, the description being "bearers." According to the general classification of goods "bearers" were chargeable at a lower rate than electrical appliances, the charge for the former being 9s. 2d. a ton and for the latter 22s. 9d. per ton. Defendants contended that they were entitled to consign the goods as "bearers," and submitted that as there was no rate fixed in respect of the consignment of a generator in parts between Birmingham and Witton at owner's risk, there was no evidence in law of an offence under sec. 99 of the Railways Clauses Act, 1845.

For the Railway Company it was argued that even if the casting of the stator itself was accurately described as a bearer, when it was filled with coils it would be part of a generator, and that the description "bearer" was a false one. They contended that defendants had falsely put the description on the stator, with the intent of obtaining a lower rate of carriage.

The magistrates held that defendants had given a false description of the goods consigned with the hope of avoiding payment of certain tolls, and imposed a penalty of £10. 10s., and costs.

For appellants, Mr. DISTURNAL argued that there was no special toll applicable to these goods.

Mr. MACASSEY (with whom was Sir Alfred Cripps) argued that the goods should have been consigned under the sections X, Y or Z, which were at owner's risk.

The LORD CHIEF JUSTICE, in giving judgment, said in his opinion the judgment of the magistrates was quite right.

The appeal was therefore dismissed, with costs.

Notting Hill Electric Lighting Co. (Ltd.)—On Tuesday Mr. Justice Neville heard a petition by this company to sanction a scheme of arrangement for the purpose of wiping out the founders' shares. Counsel for the Company said these shares formed a barrier to certain negotiations. The basis of the present proposal was to get rid of the founders' shares and bring them into the class of ordinary shares. The company would issue 27,050 shares of 1s. each, which would be issued to the existing shareholders on the footing that the ordinary preference shareholders and the ordinary shareholders should be allowed to subscribe for one 1s. share in respect of each share held, and the holders of the founders' shares should be allowed to subscribe for 24 1s. shares in respect of each share. The special voting power attached to the founders' shares would go, and each share would carry with it one vote. The scheme would do away with the present division of profits. They would have 6 per cent. cumulative and non-cumulative preference shares and ordinary shares, and the new 1s. shares would be called ordinary shares. From Jan. 1, 1911, the profits of the company would be applied in paying a 6 per cent. cumulative dividend on the cumulative preference, a non-cumulative dividend on the non-cumulative preference of a like amount, and, subject thereto, would be distributed equally amongst the ordinary shareholders *pari passu* to the amount paid up on those shares. The scheme also provided for the payment of a bonus to the preference shareholders in the event of an amalgamation, on a sliding scale ranging from £1. 19s. 4d. at the end of the present year to 2s. 11d. in 1930, which was the year fixed, as in 1931 the local authority would have power to buy the company out. The scheme had had the approval of all the shareholders with the exception of the holder of one founders' share, and he declined to vote. There was no opposition, and his lordship sanctioned the arrangement as proposed.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Alloa.—The Council recently took over the administration of the electricity works from the British Electric Plant Co., and it is now proposed to duplicate the plant at an estimated cost of £3,400.

Barnstaple.—As Mr. Albert Gay has reported that the present storage battery at the electricity works is quite inadequate, the electrical engineer (Mr. J. W. Hadfield) has been requested to prepare a specification for a new battery.

Bath.—At the Council meeting on Tuesday next the Electric Lighting Committee will recommend an expenditure of £7,500 on the electricity undertaking, including the substitution of 800 H.P. Diesel engine and a 450 kw. dynamo for some of the present steam plant. The new machinery will run the summer load, and in the winter the steam plant will supplement it. The electrical engineer (Mr. F. Teague) considers that this will effect a gross saving of £2,228, and after allowing £675 for capital charges the net saving will be £1,553.

Birmingham.—The Tramways Committee have approved heads of agreement for the through running of electric cars on the cable route between July 1 and Nov. 9, when Handsworth becomes part of the city.

Bispham.—The Board of Trade have consented to overhead line being used for the Council's electric lighting scheme. Sanction to a loan has been applied for.

Blackburn.—There was a profit of £697 on the past year's working of the electricity department, against £1,387 in 1909-10. On the tramways department there was a deficit of £181, against a profit of £453.

Blackpool.—The borough electrical engineer (Mr. Chas. Furness) has reported that the receipts on the Corporation tramways for the year ended March were £56,633. 18s. 8d., compared with £57,489. 1s. 1d. in 1909-10.

The number of passengers carried was 8,999,565. The net profit is £500. In the electricity department it is expected that the net profit will exceed £5,000.

The new promenade is to be illuminated by 10 yellow flame arcs and 40 100-c.p. Osram lamps.

Bradford.—On Monday the members of the Tramways Committee inspected a new tramcar brake which has been invented by the general manager of the tramways (Mr. C. J. Spencer). No details have yet been published.

Bridgwater.—The local electric light company has been entrusted with the electric lighting of Blake Gardens.

Coronation Illuminations.—Messrs. Pigott Bros. are to illuminate the Bank of England, London, on Coronation day (June 22), using over 5,000 electric lamps.

The Public Health Department of the Corporation of the *City of London* have issued a notice addressed to electric lighting contractors and others (a copy of which is given in an advertisement on another page) setting out the conditions with which temporary installations of electric lighting for Coronation illuminations and decorations must comply.

The Yorkshire Electric Power Co. will from June 12 to 24 inclusive supply current for Coronation illuminations to any of their customers in *Guiseley, Yeadon, Otley, Farsley, Gomersal, Horsforth, Hipperholme, Liversedge, Ossett* and *Shipley Bridge* at 1½d. per unit, plus cost of additional service mains, if required.

The Sheffield Corporation will supply at 2*d.* per unit, plus 2/6 for connection &c., from June 22 to 25.

Dublin.—An enquiry was opened on Monday into the Council's application for sanction to borrow £128,129 for extensions of the electricity undertaking.

Sergeant O'Brien, K.C. (for the Corporation) said the electricity department of the Corporation was now in charge of a Special Committee. Objections to the present proposal had been made by the Tramways Co. and others, but the Corporation courted enquiry. Up to the present £965,742 had been sanctioned in connection with contracts at the Pigeon House station, the sub-stations and other matters necessary to the supply of electricity. £137,525 had been repaid, leaving £483,217. The main question was whether the station should be scrapped and new experiments made. The total capacity of the Pigeon House station was at present 6,000 kw., and of that 1,500 kw. must be kept in reserve, leaving 4,500 kw. In December last demands requiring 4,600 kw. were made. The proposed extension would involve no loss to the city, but a very substantial gain, because up to the year ending March 31 a surplus of £7,000 could be shown. Applications for new consumers were coming in more rapidly than during the corresponding period of last year. Counsel proceeded to quote from reports by the Committee and the city electrical engineer (Mr. M. Ruddle), and stated that the extension was necessary not only on statutory, but on common-sense grounds.

Mr. Fred Allan, secretary of the Electric Lighting Committee, stated that they had 3,398 consumers last year. During the present year they were having the Richmond Asylum, South Dublin Union and the new College of Science, and they expected a considerable supply from the main drainage electric pumping station. He proceeded to supply formal evidence as to accounts, &c.

The Inspector (Mr. Cowan) commented on the fact that the Corporation had exceeded by thousands of pounds the sanction of the L.G. Board.

Mr. Allan said when the Board suggested that expenditure should not be incurred without sanction, the Corporation took the practical view that they would go on with the work which they were bound to carry out, but that would curtail speculative work.

Mr. S. L. Pearce said that he had inspected the Pigeon House and Fleet-street stations, and several of the transformer sub-stations. He had been furnished with statistical records and data relating to the general working of the undertaking. As to the general condition of the undertaking, the system in use at Dublin—three-phase generation at extra high tension and distribution through static transformer sub-stations to low-tension alternating-current networks—was quite a modern and standard one, and the general lines on which that system had been applied to the city were fairly up-to-date. Whilst being quite flexible and suitable for future extensions, it would at the same time permit of many modern improvements in plant design and economies being taken advantage of. The plant at Pigeon House generating station appeared to be in good running condition and the units up-to-date. Having regard to the output, load factor and other local conditions he did not consider the works costs unreasonably high. The distributing system generally was in a thoroughly satisfactory condition. Both the high tension and low tension networks had been well laid. It would be advisable to have fewer sub-stations, with larger transformer units installed, and that, he understood, was being done. On the advisability of extending at Pigeon House or seeking another and more central site, the present question to be decided was whether the Corporation, having acquired the site, and having spent some £160,000 on the generating station were now justified in abandoning it for some more centrally situated station. He compared the figures which the alternative plans would involve, and he held that the evidence was largely in favour of the retention of the existing site. In his opinion it was clear that the proposal to shut down the Pigeon House station would involve an additional expenditure of £150,000, on which the annual charges would amount to £11,200. On a favourable estimate the Corporation could not hope to give more than £1,000 per annum, and in face of the estimates he was unable to see that any sound financial gain could accrue to the electricity department by adopting such a radical alteration as would be involved in the shutting down of the Pigeon House station and Fleet-street and the building of a new station on another site. He had come to the conclusion that there was no reason why future extensions should not be carried out there, at any rate up to the capacity of 12,000 kw. As long as the Dublin load was what it was, viz., one made up of short-hour consumers with a very accentuated evening peak, in short, with a bad load factor, low working costs were out of the question. That condition of affairs would not be improved by shifting the generating station. The remedy or partial remedy for a poor load factor was to be sought for in other directions. The present proposals of the City Electrical Engineer were a step in the right direction for the utilisation of more efficient plant. He did not, however, advise the Committee at the present time to consider scrapping any of the Pigeon House plant. The new turbine unit to be installed this year would carry the day load more than adequately, and the reciprocating units would be held in reserve largely. He did not consider the tariff high, having regard to all local circumstances, and particularly in comparison with gas at 3s. 4d. per thousand. The bulk of the street lighting was now done by 500-watt Verity a.c. open-type arc lamps, and for the most part was a fairly typical example of commercial lighting, as originally carried out by electricity undertakings. He had noted the good results obtained from the new flame arcs in the North Circular-road and elsewhere. It would be well if the Electricity Committee were to take into early consideration the advisability of either changing the existing arcs or supplementing by new flame arcs the lighting in important thoroughfares. The illumination in the centre of these roadways did not appear to be sufficient, nor on the one side where the lighting was all done from the opposite side of the road. The street lighting of Dublin was up to the standard of other similar cities.

The inquiry was adjourned.

East London Railway.—It is announced that the Joint Committee of the East London Railway have decided to adopt electric traction. The cost is estimated at £50,000. The work will be commenced immediately, and it is hoped that it will be completed in eight months. The line consists of 5 miles 54½ chains of double track.

Festival of Empire.—In connection with the Festival of Empire at the Crystal Palace, Messrs. R. Waygood & Co. have been instructed to construct a special electric passenger lift for the use of His Majesty upon the occasions of his visits during the summer. The lift will travel from the Terrace of the Palace to the King's Pavilion, and the control will be similar to that in vogue on the London Underground Railways.

Fire.—A fire broke out on the 21st inst. at the Leyton works of the London Electric Wire Co. & Smith's (Ltd.), but the outbreak was confined entirely to a detached building in which part of the company's enamel-insulating process was carried on.

No personal injuries were sustained, and no one will be thrown out of employment. The remainder of the factory has not been affected in the slightest degree, and all other manufactures of the company are, therefore, being carried on without any interruption whatever.

Grimsby.—From the 26th inst. to May 3 demonstrations of cooking by electricity are being given by Miss G. A. Paget, on behalf of the electricity department, at the Municipal buildings.

Harbour Lighting.—Aberdeen Harbour Board have accepted the following terms of the municipal electricity department for a supply of electrical energy for five years:—

All public lighting by arc lamps to be charged at £14. 10s. per lamp per annum. Current for incandescent lighting to be at the flat rate of 2·75d. per unit. All power and heating to be at current power and heating rates. The Harbour Commissioners guarantee a total consumption of not less than 160,000 units per annum. These terms mean a reduction in the cost of electric lighting by about £150 per annum.

Heywood (Lancs.).—The accounts of the electricity and tramway undertakings show deficits for the year ended March of £2,044 and £1,403 respectively. The total income of the electricity department was £4,962, and the expenditure £3,713; while the gross receipts from the tramways was £10,964, and the expenditure £7,575. Interest and sinking fund requirements have led to the deficits.

Inquest.—An inquest was recently held at St. Helens into the death of a labourer named Bridge.

Deceased died of consumption, which it is supposed was set up by lead poisoning. He had been employed at the Corporation electricity works for several years and for some time had been engaged in painting in the subway, &c. He was taken ill last October, and had not been able to work since Christmas. The doctor who attended him diagnosed the disease as lead poisoning.

The CORONER (Mr. S. Brighouse) gave the jury a sketch of the history of the case. The coroner ordered a post mortem examination to be made by an independent practitioner, and the inquiry was adjourned until the following day.

GEORGE ERNEST GREEN, mains foreman of the Corporation electricity department, said deceased had to examine and clean the street boxes in connection with the distribution of electricity. There was a big box (2 ft. 6 in. square) and an inner box (15 in. square) and at certain times he would have to scrape the inner box and re-paint it. He did not know whether lead was a constituent of the paint. He would have to dust the lead cables before he started painting.

By Mr. HUTCHES (for the relatives): They did not use any white lead in their work. Deceased had not to scrape any lead. Deceased had complained to him of the smell of the lead getting on his chest. They were working in the sub-station, and witness, who had been painting for about an hour, said the paint had got into his stomach, and deceased said, "Yes, it gets on mine." That would be some time before Christmas.

In reply to the Coroner, Witness said several men were painting the boxes, and there was no doubt that when a man had not been painting and he went to paint for three or four hours he would feel the effects of it. With witness it was momentary, as he was all right after a bit.

By Mr. CHAPMAN (for the insurance company): Deceased had been on this work for about two years, and the only complaint he made was shortly before Christmas.

In answer to the Coroner, Mr. CHAPMAN said before an employer was liable for lead poisoning the person suffering had to produce a certificate from the certifying surgeon, but that certificate had never been produced, and the Corporation were not liable to pay anything. They paid a weekly allowance quite voluntarily. His evidence was that Bridge was suffering from lead poisoning, but that he did not die from it, and that the lead poisoning had nothing to do with the death.

Mr. J. W. WARR, chief outside assistant superintendent of the electricity department, gave evidence that there was no lead used in the paint. The only lead the man would come in contact with was the lead from the cables. In many cases there would be as many as 12 lead cables coming into one box, and they would be bonded together with another strip of lead. There might be what he would describe as an oxide of lead snuff in the boxes and he would come in contact with it by brushing the boxes.

Dr. LATHAM stated that deceased came to see him in the last week in December, when he described his symptoms, and he made a provisional diagnosis of paint colic. He saw him again at home, and came to the definite conclusion that he was suffering from acute lead poisoning. About a month later the symptoms had fairly well disappeared. The immediate cause of death was pulmonary tuberculosis, but it was certainly accelerated by the lead poisoning.

Dr. UNSWORTH, who conducted the post mortem examination, said that, in his opinion, the cause of death was pulmonary phthisis. He thought death was accelerated by the lead poisoning. But the tuberculosis was of such a character that he would have died from it sooner or later.

The jury returned a verdict that the cause of death was consumption, accelerated by lead poisoning; that while he was employed by the Corporation he suffered from lead poisoning; that the lead poisoning hastened or accelerated his death, and that the lead poisoning was acquired while he was in the employment of the Corporation.

Leeds.—The accounts of the tramways department for the year ended March 31 were presented to the Tramways Committee on Monday.

The total receipts were £370,402 (10·699d. per car-mile), traffic revenue being £364,927. 5s. 7d. (10·541d. per car-mile), against £353,860 (10·41d.). The number of car-miles was 8,308,439, and the total number of passengers carried was 80,806,270. The revenue from advertisements was £3,462, and from haulage of sand and gravel £1,659. The traffic expenses were £99,672. 2s. 6d., and included wages to drivers and conductors £71,138. 9s. 4d. Superintendence cost £1,840, cleaning and oiling cars £11,254, and uniforms and badges £2,592. General expenses (£33,239) show an increase of about £1,000, and local rates represented £21,123, compared with £18,528. General repairs and maintenance increased by £5,409, the total being £40,290, of which £8,735 was for repairs to permanent way, and £24,586 for repairs to cars. Power expenses were £22,101. The total expenditure was £195,303, which left a balance of £175,099, to which is added £1,204 for bank interest, and £4,032 for dividends on redemption fund investments, making a total of £180,335. Deducting £35,888. 17s. 6d. spent on permanent way renewals and other small sums £144,231 was left as gross profit for the year. Contributions to sinking fund came to £45,121, interest to £42,511, and income-tax £4,711, so that the net surplus is £51,886, which is to be handed over to relief of rates.

Light Railways.—The report of the proceedings of the Board of Trade and of the proceedings of the Light Railway Commissioners up to Dec. 31, 1910, have been issued.

On Dec. 31, 1909, six orders were before the Board of Trade awaiting confirmation; four of these were confirmed during 1910, and two are still held over. During 1910, 12 fresh orders were submitted to the Board by the Light Railway Commissioners for confirmation. 11 of the orders submitted, in addition to the four above referred to (making 15 orders in all) were confirmed in the course of the year, and the remaining order is still under consideration. In no case did the Board refuse to confirm an order. The orders confirmed in 1910 authorise 13½ miles of line, at an estimated cost of £76,680.

In their fourteenth annual report to the Board of Trade the Light Railway Commissioners state that 613 applications for orders to authorise light railways (including 102 applications for amending orders) have been made since the commencement of the Light Railways Act, 1896. In respect of 391 applications (including 12 in 1910) orders were submitted to the Board of Trade. Five orders are being settled; 204 applications were rejected or withdrawn; five were deferred, and nine new applications for Nov., 1910, remain to be considered. At present about 750 miles of light railways have been constructed under the Act; nearly 1,200 miles in addition have been authorised, but are not yet constructed. The main reason which accounts, in our opinion (say the Commissioners), for failure to construct lines in country districts, and also for the notable reduction in the number of proposals for new lines which followed on the equally remarkable activity of the early years is to be found in the fact that in its present form the Act does not adequately secure certain essential conditions—namely, cheap capital, cheap construction and cheap working. So far as the financial assistance of the State is extended under the present statute to light railways, it should be observed that out of £250,000 provided in 1896 to cover free grants and other "special" advances over five years, in 1910 (after 14 years) only about £140,000 had been actually advanced to seven lines with a total mileage of 68½ miles, and out of £750,000 assigned in 1896 for loans, up to and including this year only about £35,000 has been actually issued.

When it is remembered (continues the report) that the chief difficulty in all light railway schemes has been to find capital, it will be seen that the financial assistance of the State under the terms of the Act has not greatly contributed towards the construction of light railways, for the reason that the extent of such assistance, and the conditions under which it may be given, have not been found such as to enable the remainder of the capital to be raised on reasonable terms. Under the Development and Road Improvement Funds Act, 1909, advances may be made for light railways to or through a Government department, without reference to the conditions in force under the Light Railways Act; but such advances are not available for undertakings trading for profit, and, further, are we advised that we do not constitute a Government Department within the meaning of this provision. In our report of last year we referred to a point relating particularly to lines on public roads mostly worked by electric power. Under the Act it is provided that special consideration shall be given to the question whether proposals brought before us should not, under certain circumstances, be submitted to Parliament; but no provision was made in the event of the question being so determined, and

James ... that the company was prepared to fix a date for the purchase by the Corporation of the whole of the lines 32½ years hence, the company in the meantime to have possession of the whole of the tramways, including the Corporation lines.

The Committee adopted a recommendation to appoint Mr. J. M. McElroy (at a fee of 50 guineas, plus reasonable travelling expenses) to advise them on the subject.

Willesden.—On the past year's working of the electric supply department the net profit was £1,600.

Wireless Telegraph Notes.—The Bolivian Government has obtained powers to raise a loan of £50,000 for the erection and equipment of radio-telegraphic stations at La Paz, Riberalta, Cobija, Trinidad, Santa Cruz, Puerto Suarez and Gran Chaco.

It was decided some time back to establish a wireless station near Hammerfest (Norway), and it has now been resolved to open a station at Spitzbergen (probably at Green Harbour). The work will probably be completed this year. The stations, which are distant 750 miles, are to be kept open all the year round. It is anticipated that the exploitation of the Arctic circle will be greatly facilitated by the new arrangements.

It is announced that an arrangement has been come to between the Marconi interests and the French Government which will overcome the former want of agreement between the parties as to the interchange of communication between ships equipped with Marconi apparatus and ships and certain shore stations equipped with other systems of wireless telegraphy.

Wrexham.—An L.G. Board inquiry will be held here on Wednesday next into the application of the Corporation for sanction to borrow £3,345 for various works for the electricity department, including (amongst other things) the fitting out and supplying of machine tools, the erection of a coal elevator, new switchboards, public lighting, the erection of stores and offices, feed pumps and forced draught apparatus for one of the boilers. An application to borrow £800 for a battery will also be dealt with.

COLONIAL AND FOREIGN NOTES.

Australasia.—The "Australian Mining Standard" says Hobart Council (Tasmania) have referred to a committee of the whole Council a proposal that steps should be taken for the acquisition of the Hobart Electric Tramway Co.'s undertaking.

Statistics prepared by Mr. G. H. Knibbs, the Commonwealth statistician, show that the total length of tramways in the Commonwealth at June 30, 1910, was 442 miles, compared with 389¾ at the end of 1909, 275 miles are worked electrically, an increase of 23¾ miles. New South Wales has 112 miles of electric tramway and 58 miles of steam lines; Victoria is the only State where the cable system is employed, the cable lines being 46 miles, in addition to 40 miles of electric, 1 mile of steam and 13 miles of horse tramways. All the Queensland and Tasmania tramways are electric, the former having 30 miles and the latter 9 miles. South Australia has 30 miles electric, 3 miles steam and 23 miles horse. Western Australia, 53 miles electric and 23 miles horse. The Commonwealth has 213 miles under Government control (viz., 165 New South Wales, 5 Victoria, 20 South Australia, and 23 Western Australia; municipally-owned tramways are peculiar to South Australia, which has 30 miles so controlled. The total of privately-worked lines comprises 199 miles, of which New South Wales has 5, Victoria 95, Queensland 31, South Australia 6, Western Australia 53, and Tasmania 9 miles.

At Gawler (S. Australia) recently a meeting of ratepayers passed a resolution approving the Corporation borrowing £4,000 for electricity works. It was stated that the scheme proposed provided for 100 private installations. It was decided that a poll should be taken.

Giving evidence before the New South Wales Public Works Committee recently as to the expediency of constructing a railway from Wagga Wagga to Tumberumba, Mr. J. Arnot said there was plenty of water power in the district to successfully work the line by electricity. The system would cost about £127,000, including rolling stock, overhead gear and power house.

Mr. W. G. Crossle (F. A. McCarty & Co., Melbourne) has been engaged to prepare plans and estimates of cost of the electric lighting scheme proposed by the Mortlake Butter & Cheese Factory for supplying the town of Mortlake (Victoria).

Mr. E. N. Moore who presided over the inquiry into the causes of the Richmond (Victoria) railway disaster, viewed with favour the electrical signalling device of Mr. V. Russell (Rochester) and undertook to draw the attention of the Railway Commissioners to it.

A deputation of the Ballarat employés of the Electricity Supply Co. of Victoria waited upon the new general manager (Mr. P. J. Pringle) soon after his arrival, and made certain requests relating to wages and conditions of labour. Mr. Pringle has decided to make certain increases and to deal with the men's other requests later.

At a meeting of the Australian Association of British Manufacturers and Their Representatives at Melbourne on March 7 (Mr. J. Wilson, India Rubber Co., in the chair), the following were elected members of the executive council: President, Mr. Percy Rosling (W. T. Henley's Telegraph Works Co.); vice-presidents, Messrs. B. K. Morton, G. Shrimpton and Edwin Wood; councillors, Messrs. G. M. Buchanan, G. Smith Morison (Siemens Bros. Dynamo Works, Ltd.), and Irwin Hinds (Gibson, Battle & Co.).

Digitized by Google

Canada.—The bill for the construction of an electric railway from Port Dover to Galt (via Brantford, Ontario) has been passed.

The Scottish Ontario Synd. have secured from the Government the right to operate a power dam at Sturgeon Falls, on the Mattagami River, 30 miles to the north of Sandy Falls, where hydro-electric power is now being developed for the Porcupine camp.

It is reported that four electric lighting and railway companies, of a total capital of $19,000,000, are to be merged in one undertaking. The companies concerned are the Toronto Electric Light, the Electrical Development, the Toronto Power, and the Toronto Railway companies.

China.—A consular report states that a native company was recently formed for the installation of electric light works at Shasi and Ichang, and a contract had been made with a foreign company for the supply of plant capable of supplying current to 4,000 lamps at each place, but it is believed that the capital has not yet been fully subscribed, and that it is doubtful whether the scheme will go through at present.

Guatemala.—A consular report states that imports to Guatemala in 1909 included electrical material and apparatus valued at £7,910 (compared with £13,551 in 1908), machinery £38,337 (against £19,737) and scientific instruments £907 (£4,348).

St. Petersburg.—The Municipal Council have received another request for a tramway concession.

It is stated that the would-be concessionaire offers to supply £3,000,000 and procure as much again from Paris in return for a concession to construct the remaining tram lines and exploit all St. Petersburg trams for 39 years, paying a percentage of gross takings, not less than £300,000 annually, to the municipality, which will have the right to acquire the undertaking after 20 years on certain terms.

Switzerland.—An 80 years' concession has been granted to M. J. Cathrein, of Brigue, and M. a. Roemer, of Paris, for the construction of a narrow-gauge electric railway (partly on the rack and pinion system) from Brigue, via Riederalp and Eggishorn to the Aletsch glacier.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are wanted by May 19 for supply of six 60 kw. single-phase transformers, and by May 26 for 1,024,000 arc lamp carbons and for 6,000 metal filament incandescent lamps for the City of MELBOURNE electricity department. Tender forms, specification, conditions of tender, &c., from the Agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter-square Buildings, London, E.C. See also advertisements.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z., until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, engine-room crane, circulating pumps and pipes and switchboard. Specifications and drawings at the offices of the High Commissioner for the Dominion of New Zealand, 13, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to May 30 for the supply of one portable petrol-driven desiccating plant to the Postmaster-General's department in Victoria, and up to May 31 for the supply of 7,000 insulators and wire and line material to the Postmaster-General's department in SOUTH AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders will be received at the office of the Receiver-General and Director of Contracts, Valetta, MALTA, up to 11 a.m. of Thursday, May 11 for the supply of arc lamp carbons. British tenderers not having representatives in Malta must make a deposit of £10 in the office of the Crown Agents for the Colonies. Particulars, specification, &c., may be obtained at the office of the Receiver-General and Director of Contracts (Mr. C. Pace Bardon), or from the Crown Agents for the Colonies, Whitehall Gardens, London, S.W. See an advertisement.

Tenders are invited up to June 7 for the supply of 2 nauts single-core submarine cable to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS invite tenders (from manufacturers) for supply of opal lamp shades during three years, and also tenders (from manufacturers) for supply of electric gas torches during one year. Tenders by 11 a.m. on Wednesday, May 10, to the Secretary, H.M. Office of Works, &c., Storey's Gate, S.W.

SOUTH SHIELDS Corporation want tenders by May 24 for supply and erection of 1,500 kw. high-pressure steam turbine (with surface condenser and pumps) coupled to 1,000 kw. d.c. generator (with switch panel, &c.) and 1,100 kw. a.c. generator (with switch panel, &c.). Specification, &c., from the Borough Electrical Engineer.

The Corporation of HASLINGDEN invite tenders for supply and laying of extra high pressure trunk mains, with medium pressure feeder and distribution cables. Tenders to Mr. W. Musgrave, town clerk, Hsalingden, by noon Friday, May 5.

MARGATE Corporation require tenders by 1 p.m. May 8, for the electric lighting of concert pavilion and other buildings at the Fort. Particulars from the Borough Surveyor, 13, Grosvenor-place, Margate.

ST. PANCRAS (London) Borough Council invite tenders for three-phase h.t. cable and for stoneware ducts. Tenders to the town clerk, Mr. C. H. F. Barrett, Town Hall, Pancras-road, N.W., by noon, May 1.

ILFORD Council require tenders by noon May 9 for the supply of distributing switchboard, feeder cable and stoneware conduit. Specifications, &c., from Mr. A. H. Shaw, Electricity Works, Low-street, Ilford.

BARNES Council require tenders by noon May 9 for the supply and erection of combination de-oiling, softening and feed heating plant. Specification, &c., from the Engineer, Electricity Works, Mortlake.

COLWYN BAY and COLWYN COUNCIL require tenders by May 3 for one year's supply of cables and accessories, engine room stores, prepayment and ordinary meters. Forms of tender from the Clerk.

EDINBURGH School Board want tenders by 10 a.m. May 1 for the electric lighting of a new school in Duncan-street, Edinburgh. Specifications from Mr. J. A. Carfrae, 3, Queen-street, Edinburgh.

BARKING Council require tenders by 7 p.m. May 10 for extension of electricity works. Plans, &c., at the office of the Surveyor on and after May 1.

Tenders are invited up to July 25 for the supply of 12 sets of a branching multiple magneto lamp signalling switchboard, or one automatic or semi-automatic switchboard, &c.; and up to June 14 for supply of a branching multiple magneto lamp signalling switchboard at Ballarat, for the Postmaster-General's Department in VICTORIA; and up to June 14 for supply of a c.b. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA. Tender forms, &c., from 72, Victoria-street London, S.W.

The Ministry of Public Works, Constantinople, will receive tenders until July 15 for the construction of electric tramways and for electricity supply in the town of ALEPPO. Specification from the Ministry of Public Works on payment of 9s. Local representation practically indispensable.

TENDERS RECEIVED AND ACCEPTED.

Stoke-on-Trent Electricity Committee have accepted the following tenders:—

British Westinghouse Co., two 600 kw. rotary converters, and two 300 kw. ditto, £1,310; Bruce Peebles & Co., two 500 kw converters, £2,250.

20 tenders were received (varying from £884 to £1,225) for supply of generating plant and for wiring at St. Patrick's College, the Bishop's House, Cavan, and the lowest (that of Macready & Co.) has been accepted.

The tender of Sutherland & Ashman has been accepted for supply of a dynamo, switchboard, and battery to the Tatura Factory Co. for the public lighting of Tatura (Victoria) at £1

The Chloride Electrical Storage Co. have secured the contract for a storage battery of 250 cells (1,200 ampere-hour capacity), booster and switchboard, for the Leith Docks.

Salford Corporation received four tenders for the supply and erection of fire and police alarm street boxes and switchboard; the contract has been let to the Gamewell Fire Alarm Co.

Southend Corporation have accepted the tender of the Darlington Eastern Steel Co. for supply of 750 tons of steel rails, at £6 per ton.

Southend Council have accepted the tender of Calleade Engineering and Construction Co. for 20 tons of copper cable.

Aylesbury Council have accepted the tender of E. T. Wright & Son for electrical work for a year.

Edinburgh Corporation have again accepted the tender of the Sebastian Meter Co. for a years' supply of 5 ampere meters.

Pigott Bros. have secured the contract for electric illumination at the Bank of England on Coronation day.

Digitized by Google

The New South Wales Government received 24 tenders (from 12 firms) for coal loading plant (capable of putting 750 tons of coal per hour into vessels) for the jetties at Port Kembla (N.S.W.).

The tenderers included English, German, American and Australian firms, and although alternative tenders were submitted, the tenderers are agreed that the general lines laid down by the chief engineer of Harbours and Water Supply (Mr. E. M. de Burgh), for conveyors similar to those at the N.E.R. Co.'s Hull Docks, were the most suitable. The tender of Kelly & Lewis (about £30,000) has been approved by the Minister in charge of the Department. The tenderers also included Armstrong, Whitworth & Co., Spencer & Co., Robins & Co., and the Jeffrey Mfg. Co. (U.S.A.). The plant will be operated electrically.

Electricity in Rolling Mills.—Messrs. Crompton & Co., London and Chelmsford, have received a contract from Messrs. Vivian & Sons, of Hafod, near Swansea, for the electrification of their copper rolling mills. The rolls, which are continuous running, are to be driven by two 300 H.P. motors running at a speed of 150 revs. per min. The contract also includes a 1,000 ampere storage battery with automatic reversible booster of the Chelmsford type. The battery is provided to deal with the peak loads of the motors and give a steady load on the generating plant. A complete set of switchgear and cable work is also included. The motors will drive the mills through cut double helical gear.

Electric Power Plant.—The Darlington Forge Co., which is extending its power plant, have placed an order with Messrs. C. A. Parsons & Co. for a 750 kw. direct-current turbo-generator.

The turbine, of the mixed pressure type, is designed to give full output at 150 lb. per square inch, vacuum 28 in., and will use with full efficiency high pressure steam at 140 lb. per square inch whenever the supply of exhaust steam is insufficient, the high and low pressure parts of the turbine being combined in one casing. The three existing Allen engines are each coupled to 250 kw. generators, and will run non-condensing and supply steam to the turbine, provision being made for them to exhaust direct to the condenser in times of light load. The dynamo is of the four-pole type, fitted with compensating winding and carbon brushes, and supply current at 220 volts.

BUSINESS NOTICES.

The trade of Messrs. Vickers, Sons & Maxim, River Don Works, Sheffield, and at London, Barrow-in-Furness, &c., has now been converted to Vickers Limited.

Messrs. Babcock & Wilcox (Ltd.) have removed their Calcutta offices into Clive Buildings, 8, Clive-street.

The Adams Mfg. Co. have concluded arrangements with Messrs. Bruijn & Wuthrich, Technisch Bureau, Haarlem, to act as their agents for Holland and Java, for the sale of their motor starting and controlling apparatus.

Messrs. Lawley Pinching and Walter Hy. Walton, electrical engineers, 32, Cannon-street, London, E.C., have dissolved partnership, and Mr. Walton, who continues as Pinching & Walton.

Messrs. Rodgers Bros. have acquired as a going concern the gear cutting business of J. B. Hamilton & Co., which they have joined to their own business of gear specialists and general engineers. They have recently erected modern works at Baker-street, Enfield, London, S.W., and have appointed Mr. P. F. Brittain (who has been associated with Messrs. Hamilton) as their sole agent for the sale of their gears, with offices at 110, Cannon-street, London, E.C.

Patents Development.—The proprietors of the following British patents desire to license British manufacturers to work same in Great Britain:—

No. 11,847/07, for "A telephonic dictating system."
No. 21,253/07, for "Telephone transmitters."
No. 11,443/02, relating to "Sound concentrating and focussing apparatus."

Particulars in each case from Messrs. Boult, Wade & Tennant, Chartered Patent Agents, 111 and 112, Hatton-garden, London, E.C.

Kelly's Manual of Electrical Undertakings.—Each succeeding issue of "Kelly's" Manual of Electrical Undertakings and Directory of Officials, which is compiled under the direction of Mr. Emile Garcke, M.I.E.E., F.S.S., shows an expansion and an increase in interest, and the 1911 issue (Volume XV.) of the work is no exception to the rule, as it contains statistical and general technical information about 3,000 undertakings. For all matters relating to the financial position of electric lighting and power undertakings, electric railways and tramways it is undoubtedly one of the most valuable works we are acquainted with. The information and statistics are the latest available in every case, and the whole bears evidence of careful compilation.

The information is classified into eight sections, viz., Electric Lighting and Traction, Telegraph and Telephone, Manufacturing Companies, Colonial and British Possessions, List of other Companies registered since 1856, Directories of Officials, Members of Electric Lighting and Tramway Committees and of Electrical Contractors, Index of Undertakings and Buyers' Guide. It is impossible to do justice to the Manual in the space at our disposal, but it may be stated that sections I. to V. contain a record of all electrical companies formed under the Joint Stock Acts and of all electrical undertakings belonging to Local Authorities in Great Britain and Ireland, and of electrical undertakings in the Colonies and all British Possessions. The section devoted to "Progress of the Year" contain much interesting historical and other matter, and there are useful comparative summaries covering the financial results of electric lighting and traction undertakings, summaries of the 1911 Bills and Provisional Orders, many interesting maps of tramway systems, &c. The Manual forms a very valuable work of reference, and it is published at 21s. nett by the Electrical Press (Ltd.), 37 and 38, Strand, London, W.C.

Typewriter Progress.—One of the most popular typewriters in use in this country is the Bar Lock. In the latest form of this machine many useful and novel features have been introduced, and the machine, always in the front rank, is more than ever deserving of the position. There is no better indication of good business and good progress than the extension of business premises, and this is the gauge of the business activity of the Barlock Typewriter Co., and its indefatigable managing director, Mr. W. J. Richardson. The Company has just moved into handsome new offices and factory premises at Bar Lock Buildings, Southwark-street, London, S.E., and Prices-street, Southwark, S.E., respectively, where there are four telephone lines (6,747 City). The show rooms remain at 12 and 14, Queen Victoria-street, E.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

The adjourned first meeting of creditors in the bankruptcy of Walter Wm. Crawford, consulting engineer, 22, Henrietta-street, Covent Garden, W.C., took place on Tuesday.

Liabilities were returned at £21,229 with a deficiency of £3,631. Debtor attributed his insolvency to loss and liabilities incurred in connection with companies (including the Crawford Electric Lamp Synd.) and other undertakings in which he had become financially interested, and with which he became connected in the course of his business.

Alphonse C. A. Wampach, electrical engineer, Formby Lodge, Seabrook-road, Hythe, has been adjudicated bankrupt.

A meeting of creditors of Arc Lamps (Ltd.) (in liq.) will be held at the offices of Messrs. Corfield & Cripwell, Balfour House, Finsbury-pavement, London, E.C., on May 9.

The discharge of Jas. Marshall Vaughan, electrical engineer, Three Queen's-lane, Bristol, is suspended for two years, ending March 24, 24, 1913.

The Rhondda Tramways Construction Synd. (Ltd.) is being wound up voluntarily. Mr. L. B. Schlesinger, 21, Cornhill, London, E.C., and Mr. W. B. Cowrie, Queen Anne's-chambers, London, S.W., have been appointed liquidators.

A meeting to receive an account of the winding up of the Synchronised Electric Clocks C. (Ltd.) will be held on May 31 at 11, Waterloo-place, Leamington Spa.

A meeting to receive an account of the winding-up of the Sylverlyte Electric Lamp Co. (Ltd.) will be held on May 27 at 46, Culverden-road, Balham, London, S.W.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

February 21, 1911.

4,332 FOURNIER-D'ALBE. Selenium cells.
4,356 LAUDER. Securing shades and lamps to electric lamp sockets.
4,385 JUSTICE. (American Automatic Switch Co., U.S.) Operating electric railway tracks, points and switches.*
4,397 OESTERREICHISCHE DAIMLER-MOTOREN-AKT.-GES. Overhead electric trolley wire construction. (Convention date, 22/10/10, Germany.)*
4,405 KARAVODINE. Secondary batteries or storage cells.
4,414 GROTE. Electric sounders.

February 22, 1910.

4,431 ROBERTSON. Electric signalling system for railways and the like.
4,443 HALL. Sparking points in sparking plugs for internal combustion engines.
4,444 BENNETT. Tram-rails and the like.
4,457 ELECTRIC & ORDNANCE ACCESSORIES CO. & COLLINS. Time-limit or retarding devices for use in connection with electric circuit breakers.*
4,488 CHAMBERS. Transmitter for signalling by electromagnetic waves
4,491 KENT & MITCHELL. Supporting or suspending electric lamps and the like.
4,498 KOTYRA. Electromagnetically controlled perforating mechanism.*
4,521 PETO & RADFORD & GENESE. Combined double and single pole switch.

February 23, 1911.

4,602 TIMAR & PRESSER. Closing of the seams of tubes by electrical resistance welding. (Convention date, 20/5/10, Germany.)*

25,964 SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke Ges.) Starting and speed regulation of polyphase electric motors.
30,138 B.T.-H. CO. (G.E. Co., U.S.) Electric rail bonds.

COMPANIES' MEETINGS AND REPORTS.

Indo-European Telegraph Co. (Ltd.)

The forty-fourth ordinary general meeting of this Company was held yesterday under the presidency of Mr. CHARLES HOLLAND.

The SECRETARY (Mr. John I. Bethell) read the notice calling the meeting and the auditors' report.

The CHAIRMAN said: Gentlemen, the year 1910 has been an uneventful one and, a matter that probably interests you more closely, a prosperous one, as you will have seen from the accounts in your hands. We have, I am glad to say, been singularly free from interruptions. The trouble that was chiefly exercising our minds last year—namely, the breaking by trawling vessels of the cables upon which we rely for our communications across the North Sea—has not visited us this fishing season, a thing for which we must be thankful. It is, however, none the less evident to the Directors that additional accommodation is required in that direction, and we are still in communication with the General Post Office on the subject. Cables are always liable to breakage from this cause, and the trouble may recur during any fishing season, when one or more cables may be interrupted. It is then that the necessity for additional facilities is most felt. We have been free from interruptions even in the most troublesome portion of our system, in South Russia, except for a period of 10 days during February last, when our wires in the Caucasus collapsed under the weight of snow, which lay to a depth of from 5 ft. to 10 ft., the result of a succession of blizzards of unprecedented severity. Once this was made good, and thanks to the efforts of our maintenance staff it was done very quickly, our troubles came to an end, and we have, I am glad to say, had no serious recurrence. The Directors still intend, when a favourable moment arrives, to add to our carrying capacity throughout our system, and have recommended a further appropriation with this object. Our daily direct working London-Karachi continues to be a most valuable asset, and it is really wonderful how much traffic can be carried in this manner with the accommodation at our disposal. The necessary assumption is, of course, that a long line, such as ours, of 4,000 miles, must be kept in the highest state of efficiency in order to fulfil it object, and that, I am glad to say, is the case. Our esteemed friend, Mr Stratford-Andrews, the Managing Director, is continually experimentin with new methods and new instruments, and you may rely upon it tha everything he can introduce to do justice to the traffic is done.

There have been no serious reductions of tariffs during the year, but should mention that the Directors have with pleasure signified their con currence in proposals placed before us, in common with other companie by the Postmaster-General, to enable senders of telegrams in plain la guage to do so over certain routes at considerably reduced rates, subje only to deferment to the daily general class of fully-paid telegrams. Th proposal was considered by a committee appointed by those interested, which Mr. Stratford-Andrews was a member. The details still remain be worked out. The casual sender of the usually short telegram of family or social nature will have things made easier for him. The me chant, with his complex codes, is already, in our opinion, sufficient provided for. Our receipts from traffic continue to be very satisfacto not only those from what we used to regard as our mainstay—namely, t Indian and trans-Indian traffic—but from the South Russian, Turk and Persian traffic. The pronounceable-combination system of code still with us unfortunately, and adds not only to the number of offic repetitions asked for, which is an ever-increasing evil, but to the anxie of the clerks who transmit them. The Directors have recognised good work done by them and by the officers and staff generally by vot them a bonus of about £3,400. We think it is fitting that the staff sho at reasonable intervals of time receive some encouragement of this k when things are going well with the Company. I may mention that last bonus was distributed six years ago.

Turning to the accounts in general, the revenue from message rece and other sources, as shown in the revenue account, shows a satisfac increase of £9,945. 6s. 3d. The combined commercial and maintena expenses show an increase of £2,573. 3s. 4d., which, however, is expla by the inclusion of the bonus to the staff of £3,406. The balance-sheet tains no additional features calling for remark, though the item of sur credit balances shows an increase over last year of about £22,000, the item of which is the £15,000 allocated during last year towards increa the carrying capacity of the system and not yet expended. The Direc after providing £4,627. 13s. 8d. for depreciation of investments durin year, propose the usual final dividend, absorbing £14,875, and bon 20s. per share, or £17,000, and have again decided to recommend a s distribution out of interest upon certain investments and advanc counts of 15s. per share, free of tax in each case. There remains a cient surplus to enable them to propose the allocation of a sum of £2 towards the cost of increasing the carrying capacity of the system, brings the fund available for that purpose to £35,000. It has not found necessary at present to make any further grant to the retire fund, which is already represented by investments to the total va over £40,000—a result which, thanks to the generous contributions shareholders, will go far towards the object required of it. We, fore, carry forward to the credit of 1911 the sum of £11,327. 10s. is all I have to say as to 1910. The three working months of 19 which figures are available, show an increase of revenue, even figures lain before you to-day, so that, assuming that working con remain favourable during the rest of the year, you may possess you in peace.

On the subject of our Articles of Association, the Company's sol who have often directed our attention to this matter, have now mended that the entire set of articles should be re-drafted. With t

Digitized by Google

directors have expressed their agreement, and the work has been taken in hand. These will be presented to you for adoption at an Extraordinary General Meeting, to be held at an early date. I now move the adoption of the report and accounts, and the declaration of the dividend, bonus, and special distribution set out therein.

Sir WILLIAM R. BROOKE, K.C.I.E., seconded the resolution, which was carried unanimously.

The re-election of the retiring Directors, Mr. J. H. Tritton and Baron Julius von Berenberg Gossler was then approved, and the retiring auditors were re-appointed.

A cordial vote of thanks to the Chairman, Directors and staff, to which the Chairman returned thanks, brought the proceedings to a close.

BABCOCK & WILCOX (LTD.)—At the meeting on Friday the chairman (Mr. J. Newrance) said that the net profits for 1910 were £362,360, compared with £360,000 in 1909, although the output had been considerably larger. After payment of a dividend of 3 per cent. on the preference shares, a dividend of 8 per cent. on the ordinary shares, and a bonus of 8 per cent. on the ordinary shares, and placing £100,000 to reserve, £25,000 to dividend equalisation fund, and £10,000 to staff pensions fund, the balance (£63,642) was carried forward. During the year the Company had made many improvements in the works, and, in the way of carrying out the work, great improvements had been made in the quality of various articles and reducing the cost. All these benefits had been given to consumers of their goods, as the net profits were not so large as in previous years. That was, unfortunately, the trend of many industrial concerns, and it was what the shareholders must expect in the future.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT CO. (LTD.)—At the meeting on Wednesday the Chairman (Mr. H. R. Beeston) said that they were recommending a dividend of 8 per cent. The number of passengers carried was 32,040,276, an increase of 2,686,938. The increase in car-miles run was 1,235,238, or 6·09 per cent. The increase in working expenses was 10·18 per cent. due partly to increased mileage and partly to increased cost of stores, owing to the general rise in wages. Many newly-erected houses with wool stores were now taking current from them. The Queensland Steamship Co. was installing an electric crane and the new premises of the Loan & Mercantile Agency Co. and the Australian Estates Co. had installed electric wool conveyors and stackers, all operated from their station. The prospects for the current year were good. Their receipts for the first quarter of the current year showed a total increase of £6,061.

BRITISH WESTINGHOUSE ELECTRIC & MFG. CO. (LTD.)—The report for the year ended Dec. 31, 1910, states that there has been a considerable improvement in the volume of business obtained during the year, and though, owing to severe competition, the prices obtained have not been higher, the results of the year's trading show a considerable advance on previous years. The trading, &c., profits amount to £98,198. 11d., from which fall to be deducted depreciation on buildings, plant, &c., £24,423. 11s. 6d. (in addition to £5,550. 8s. 1d. for renewal depreciation), expenses on surplus land and buildings, £4,784. 13s. 3d., interest on 6 per cent. prior lien debentures, and on 4 per cent. mortgage debenture stock (£49,654. 2s. 4d.), leaving a balance of £18,738. 12s. 8d. From this balance has to be deducted the amount required for prior lien redemption fund (£5,642), and the expenses of issue of prior lien debentures (£660), leaving £12,436. 12s. 8d. Deducting from this the debit balance brought forward, £7,319. 12s. 8d., there is a net credit balance of £5,117. 0s. 8d., which the directors should be carried forward. A substantial sum has been written off out of revenue during the year for maintenance of buildings, machinery and plant, and £24,423. 11s. 6d. further has been applied to the redemption of some items. During the year the increased demand for the goods shown by the export market has continued, and has extended to the home market. The orders for the current year show a considerable increase over those for the corresponding period of 1910. At the annual meeting reference was made by the chairman to a pending arbitration for a large sum. The award was given in March last, and has been entirely adverse to the company. The directors have been advised to appeal, and the matter is, therefore, still sub judice. The following gentlemen have been elected to seats on the board to fill existing vacancies:—Messrs. Norman B. Dickson, C. A. Park and W. W. Blunt.

CITY OF BIRMINGHAM TRAMWAYS CO. (LTD.)—After providing for the year's interest on debentures and the dividend on the preference shares paid and accrued up to Dec. 31 last (£10,000), the profit shows a surplus of £44,327. 7s. 4d.; deducting interim dividend at the rate of 10 per cent. per annum paid on the ordinary shares for the six months ended Sept. 30 (£6,314), the disposable balance is £38,013. 7s. 4d. The directors recommend that the surplus be applied in a dividend on the ordinary shares at rate of 10 per cent. per annum for the three months ended Dec. 31 last (making, with the interim dividend paid, 10 per cent. for the year), the balance (£36,513. 5s. 4d.) being carried to reserve. £4 per share on the fully-paid ordinary shares has been repaid, and the directors offered to accept the £4 10s. per share repaid as money paid in advance of calls, and to allow interest at 4 per cent. per annum. £7,252 has been deposited under this arrangement. The traffic receipts, compared with the previous year, show an increase of £3,766. 2s. 9d., while the receipts from sources other than interest on investments show an improvement of £4,000. On June 30 next the company will lose several routes, including the cable tramway and the tramways in Harborne roads, owing to the expiry of leases from the City Council and the Councils of Handsworth and King's Norton. The Corporation have in view the construction of electric tramways, and in consequence of the uncertain value of the investment in the Birmingham & Midland Motor Omnibus Co., the directors recommend that it should be written down out of reserve to £5,000. Negotiations have proceeded with Handsworth Council in regard to the terms and conditions of the lease of the cable tramways, but, failing agreement, the matter was submitted to the arbitrament of the Right Hon. A. Lyttleton, K.C., and the terms of the lease for working the lines until June 30, 1911, have been settled. Negotiations have been continued with Aston Corporation to settle the terms of the lease to be taken by the company of the tramways in Aston, but the matter is not yet concluded.

CITY OF BRISBANE ELECTRIC LIGHT CO. (LTD.)—At the recent meeting it was reported that the result of the half-year's working, to Jan. 31, was a credit balance of £5,341. 19s. 5d. After payment of the preference dividend, the directors recommend a dividend at the rate of 10 per cent. on the ordinary shares and at the rate of 10 per cent. on the contributing shares. Also a bonus at rate of 2½ per cent. on the ordinary and contributing shares. The balance forward was £2,179.

ELECTRICAL DISTRIBUTION OF YORKSHIRE (LTD.)—Mr. R. W. Wickham, who presided at the meeting on Tuesday, said that there had been a considerable increase in the number of consumers during 1910. At the beginning of the year 83 applications had been received, and at the end of the year they had 201. Applications were still coming in in the same satisfactory manner, so that a further increase in the profit available for dividend might be reasonably anticipated as a result of this year's trading. There had been no increase in the number of shares allotted, but the amount owing to sundry creditors had grown from £5,363 to £9,877. That had been mainly caused through capital expenditure incurred in laying mains and in additional service mains in districts where a supply was commenced before 1910. The directors had made temporary arrangements with the Yorkshire Electric Power Co. to borrow capital sufficient to commence the development of the Distribution Company's undertakings. The Power Company had shown their confidence in the future of that company by agreeing to take ordinary shares at par in payment of the greater part of the amount owing at the end of 1910, bringing up the issued share capital to £17,000. A dividend at the rate of 2½ per cent. was declared.

WM. GRIFFITHS & CO. (LTD.)—At the meeting on Wednesday the Chairman (Mr. R. H. Burdett) regretted that the result of the year's trading had not been more favourable. The rearrangement of the capital was successfully carried out and every share in the old company had been exchanged. During the past few months they had secured a considerable amount of work, and he was hopeful that this year would result in a considerable increase in turnover and in profits.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAY (LTD.)—The directors' report for 1910 states that the total revenue was £31,008. 15s. 2d., and the expenditure (including £1,600 for debenture interest and £1,000 placed to renewals account) amounted to £24,174. 3s. 5d., leaving a net profit of £6,834. 11s. 9d., which, added to £66. 19s. 10d. brought forward, makes an available balance of £6,901. 11s. 7d. The directors propose that £1,250 be placed to reserve, and after paying dividend at rate of 5 per cent. per annum on the cumulative preference shares (£2,500), a dividend on the ordinary shares at the rate of 7 per cent. per annum for the six months ended Dec. 31 (making with the interim dividend paid on August 15, 1910) 6 per cent. for the year) (absorbing £3,000), leaving £152 to be carried forward. The state of trade in the district during the year was unsatisfactory, and there was a decrease in traffic receipts, compared with 1909, of £56. 7s. 4d. Owing, however, to economies effected the net profit has been increased by £467. 10s. 5d.

ORIENTAL TELEPHONE & ELECTRIC CO. (LTD.)—At the meeting on Monday the chairman (Mr. B. St. John Ackers) said that the proposed dividend (8 per cent.) was a handsome one. The increase in their business continued unabated, and they could not escape further large outlays of capital. Considerable expenditure had to be incurred last year for new construction at their exchanges at Rangoon, Madras, Singapore, &c., and was continuing this year, while a further £10,000 was advanced to the Bengal Telephone Co. for their most urgent extensions. The proposal to take over the present Government telephone system in Calcutta and to supply the Government in future with all telephone accommodation required was of much importance. It was only prudent to keep in hand any funds not required for their own extensions; so that if an agreement with the Indian Government was eventually reached, the necessary funds might be forthcoming to complete the purchase. Spread over the next few years a considerable capital outlay would also be required for Mauritius, where they had secured a 30 years' concession for the whole island. The revenue to accrue from that outlay was, they considered, satisfactory. Owing to those calls on their resources a larger dividend than 8 per cent. was not at present desirable.

PEARSON FIRE ALARM (LTD.)—At an extraordinary meeting on Monday a scheme for the amalgamation of the undertaking with the May-Oatway Fire Appliances (Ltd.) and the formation of a new company to be called Automatic Fire Alarms (Ltd.) was approved. The chairman (Mr. A. D. Fairbairn) said that the two companies protected property valued at £50,000,000. It was hoped that, as a result of co-operation, they would be able to induce the tariff insurance companies to increase the inadequate rebate allowed to those who used fire alarms, and when the amalgamation was completed an application for an increased rebate would be pressed. The amalgamation would also enable them to obtain better terms from contractors and to institute considerable economies. The shareholders of the May-Oatway had approved the scheme.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—The net revenue for 1910 was $5,433,576 after deducting operating, maintenance and other expenses in Rio de Janeiro. The fixed and other charges of the subsidiary companies and the fixed charges, interest and general expenses of the company, amount to $3,096,434, leaving a surplus of $2,337,142, making with the amount brought forward ($1,707,935) a total of $4,045,078. The board have appropriated $250,000 as sinking fund on the first mortgage bonds, $300,000 to general reserve, two quarterly dividends of 1 per cent. each and two of 1½ per cent. each (absorbing $1,462,438) have been paid and the balance ($2,032,640) has been carried forward. As the tramway construction was completed in the first quarter of the year and the remainder of the lines operated by mule traction discontinued on March 26, 1910, construction during the period under review has consisted chiefly of the extension of the electric light and power distribution systems in the city and federal district and the erection of the new gas works. As a result of the complete electrical equipment of the entire system, the operation of the tramways department has been conducted in a much more efficient, rapid and economical manner than in previous years, with the result that the service has been very satisfactory and the gross revenue has steadily increased. The suburbs are rapidly growing, due to the increased facilities afforded by the tramways, and this should very materially increase the revenues of the suburban tramway lines in the next few years. During the year 68 13-bench motor cars were manufactured in the company's shops and put into service, and a large addition has been made to the company's equipment in its freight department. The tramways of the Jardim Botanico Co. are now consolidated with this company's system under an operating contract. By the consolidation of the two systems and the substitution of hydraulic power in place of steam on the Jardim Botanico system, a material saving in the cost of operation has been effected.

The business of the telephone department has progressed satisfactorily, there being 4,859 subscribers connected up on Dec. 31, 1910 against 3,991 in 1909. The reconstruction of the old telephone service has been continued, the greater part of the lines having been rebuilt, and a large amount of new work has been done to meet the growing demands in the suburban districts. The central sub-station in the Villa Isabel and Jardim Botanico districts have been completed, bringing up the total switchboard capacity to 8,700 lines.

The electric light and power business continues to grow in a satisfactory manner—the distribution system in the underground and overhead sections has been greatly extended with the necessary transformer equipment and low-tension lines. At present the company has installed 30,589 kw. capacity in transformers connected to its overhead and underground systems. There have also been installed 2,905 street arc lamps in accordance with the terms of the gas concession, making a total of 3,522 street arcs in operation. While the sales of gas have not increased materially during the year, owing to competition from electric light, there has been a satisfactory increase in the number of consumers.

RIVER PLATE ELECTRICITY CO. (LTD.)—After providing for administration expenses, bad debts and all necessary depreciations, the accounts for 1910 show a balance of £45,026. 9s. 7d. Interest on the 5 per cent. debenture stock requires £10,000, leaving a surplus of £35,026, which, with £5,141 brought forward, made an available balance of £40,167. The directors propose that this sum be appropriated in paying a dividend at the rate of 6 per cent. for the year upon the preference stock and shares (£7,403) and a dividend of 10 per cent. for the year upon the ordinary stock (£12,000), adding £14,000 to general reserve, paying £875 as further remuneration to the directors and carrying forward £5,889. The whole share capital of the Rosario Electric Co., in which the company, since its formation, has held a large interest, has been purchased by the Société Financière de Transports et d'Entreprises Industrielles. This company received a price for its shares in excess of the price at which they were originally acquired and stood in the books of the company, and in respect of the transaction £41,000 has been transferred to general reserve, which now amounts to £85,000. The business, both at La Plata and Tucuman, has continued to grow throughout the year, and the prospects of further business in the current year are encouraging. In addition to the contract with the La Plata Electric Tramways Co. for the supply of power, the directors have recently concluded a contract with the National Tramway Co. of La Plata for the supply to that company of all the power necessary for its system. When the electrification of the latter (now in progress) is completed, the River Plate Co. will supply the entire tramway systems of La Plata and Ensenada. The erection and equipment of the important new generating station at Ensenada is nearing completion, and it will be in service in the early autumn.

SOUTH METROPOLITAN ELECTRIC TRAMWAY & LIGHTING CO. (LTD.) Mr. C. G. Tegetmeier stated at the meeting, on Tuesday, that the result of the year's working had been a surplus of £20,245, compared with £16,113 in 1909. They had a distinctly improving property. The scope for the reduction of working expenses was limited in one direction by the fact that they were compelled to take all their current from Croydon and Beckenham Councils. The company would make a considerable saving if they could generate current for themselves.

WEMYSS & DISTRICT TRAMWAYS CO.—The traffic receipts for 1910 were £13,576, a slight decrease compared with 1910. The total income for the year was £13,843, and, after paying interest on mortgage debenture stock, providing for depreciation and writing off £350 for special expenditure, the balance was £2,573, which is increased to £2,875 by adding the balance forward. The directors have paid the 6 per cent. dividend on the preference shares (£1,800), and they propose that the ordinary shares should be paid 6 per cent., leaving £275 to be carried forward.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c,

NEW COMPANIES.

MERSEY POWER CO. (LTD.) (114,319.)—Reg. April 15, capital £250,000 in £1 shares, to acquire from G. H. Cox and H. J. Falk all or part of the undertaking authorised by the Runcorn Urban and Runcorn Rural Electric Lighting Order, 1910, from Widnes Corporation all or part of the undertaking authorised by the Widnes Electric Lighting Orders, 1901-10, and the benefit of a certain agreement. First directors are G. H. Cox, W. H. Alexander and H. J. Falk. Reg. office: Colonial House, Water-street, Liverpool.

RESISTO-ELECTRICAL ENGINEERING CO. (LTD.)—Reg. April 18, capital £7,500 in £1 shares, to carry on the business of manufacturers of and dealers in electrical apparatus of all kinds. Private company. H. W. Quittenden is the first secretary.

STATUTORY RETURNS.

ELLIS & WARD (LTD.)—Return to April 3 gives capital £10,000 in £1 shares. 6,003 shares taken up. £3 paid. £6,000 considered as paid on 6,000 shares. Mortgages and charges, nil.

LONDON ELECTRIC WIRE CO. & SMITHS (LTD.)—In return to March 8 capital is £420,000 in 70,000 ordinary and 14,000 preference shares of £5 each. 64,407 ordinary and 10,000 preference shares taken up. £35 paid. £372,000 considered as paid. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

ALBERT DICKINSON (LTD.)—Particulars of £300 debentures, created April 12, have been filed, the amount of present issue being £200. Property charged: company's property, present and future, including uncalled capital. No trustees.

COWPER-COLES INVENTIONS DEVELOPMENT CO. (LTD.)—Particulars of £1,000 debentures, created by resolutions of June 1, 1906, and March 29, 1911, have been filed, the amount of present issue being £320. Property charged: company's undertaking and property, present and future, including uncalled capital. No trustees.

GAVAN INRIG (LTD.)—Particulars of £500 debentures, created March 14, have been filed, amount of present issue being £150. Property charged: company's undertaking and property, present and future, including uncalled capital. No trustees.

KILOWATT PUBLISHING CO. (LTD.)—Issue on April 1 of £112. 10s. debentures, part of a series of which particulars have already been filed.

SUN ELECTRICAL CO. (LTD.)—Particulars of £7,000 debenture stock, created by resolutions of March 21 and 31, and secured by trust deed dated March 31, have been filed, the amount of present issue being £6,875. Property charged: company's undertaking and property, present and future, including uncalled capital and leasehold premises. Trustees: R. T. Smith and H. Samson.

CITY NOTES.

MEMORANDA (April 27).—**Bank rate** 3 per cent. (March 9, 1911). **Price of silver,** 24⅛d. per oz. **Consols** 80⅞—81 for money; 80⅞—81⅛ for account. **Consols Pay Day,** May 4; **Stock and Shares Continuation Days,** May 10 and 29; **Ticket Days,** May 11 and 30; **Pay Days,** May 12 and 31; **Mining Shares Carry Over Day,** May 9.

PRICES OF METALS (London).—*Copper*, cash, 54⅞; three months, 54⅜. *Lead*, English, 13½—13⅝; foreign, 12⅞—12⅜ cash, 12⅜—13⅛ three months. *Spelter*, 23⅞—24⅛. *Tin*, English, 193—194; foreign, 194¾ cash, 190½ three months. *Iron*, Cleveland, cash, 46/6½, three months, 47/3.

CITY OF BUENOS AIRES TRAMWAYS CO. (LTD.)—The directors have declared a dividend of 1s. 3d. per share for the three months ended March 31.

COLOMBO ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—The directors have resolved to pay a dividend of 8 per cent (tax free) for the year 1910, carrying forward £3,710. The sum of £8,300 has been transferred to reserve and renewal fund.

CUBA SUBMARINE TELEGRAPH CO. (LTD.)—A dividend is announced at the rate of 6 per cent. per annum, tax free, on the ordinary shares, for the half-year ended Dec. 31.

GENERAL ELECTROLYTIC PARENT CO. (LTD.)—For the year ended Jan. 31 the accounts show an available sum of £6,447. The directors recommended a dividend of 5 per cent., £5,017 being carried forward.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed May 4 a special settling day in 150,000 £1 fully-paid shares of *Metalite (Ltd.)* and have granted a quotation to $5,000,000 capital stock of the *Manila Electric Railroad & Lighting Corpn.* The Committee have granted a quotation to a further issue of £21,000 4½ per cent. first mortgage prior lien gold bonds of the *Montreal Water & Power Co.*

SUBMARINE CABLES TRUST.—Notice is given that 21 certificates will be redeemed from the surplus funds of the Trust by a drawing which will take place on May 4, at 34, Electra House, Finsbury-pavement, London, E.C., for payment at £120 per certificate at Messrs. Glyn, Mills & Co.

TRAMWAYS & GENERAL WORKS CO. (LTD.)—The accounts for the year ended March 31 show an available balance of £1,161. A dividend of 1s. per share is recommended and £161 carried forward.

NOTES.

The Wireless Telegraph Situation.

The situation in the world of commercial wireless telegraphy is changing rapidly at the present time, the latest event being the granting of a new patent to Sir Oliver Lodge extending for another seven years certain claims of his well-known patent No. 11,575 of 1897. It is quite reasonable that certain pioneer patents should be extended, for it is generally an uphill task to gain adequate reward from them in the time originally allowed; and thus it would not be surprising if a similar extension of life were given to some of the Marconi patents in due course. The judgment of Mr. Justice Parker in regard to Lodge's patent is given at length elsewhere in this issue, and may be described as a model *résumé* of the main features disclosed in the specification. This summary is of value in that it enables us quickly to seize upon the points that count to the legal mind. The claims of the new patent which appear likely to affect the wireless situation are Nos. 1 and 2, and 6 and 9 of the original patent. As regards claims 1 and 2, a great deal will depend upon how broadly these are interpreted by the courts. Claim 6 is the one which possibly presents the greatest interest at the moment. This relates to the means of charging the transmitter by impulsive rush without metallic connection with the source of supply. This impulsive rush method was recently hailed by Mr. Duddell as the anticipator of the Wien shock excitation method, and if this be so, the use of the quenched spark may turn out to be controlled by this patent.

While the object achieved is, however, to some extent the same, namely, the provision of means whereby the oscillator will continue oscillating freely, the question whether the methods of the impulsive rush and the quenched spark are identical, may require thrashing out in a court of law. For the term "shock" excitation, though it has caught on, is really a misnomer; what takes place in the quenched spark is a transfer of energy at each spark (which is an ordinary and not a B spark), through the medium of the interlinking, and the only shock really is the suddenness of the extinction of the discharge—the oscillator then continuing with its very slightly damped oscillations. With the impulsive rush method, on the other hand, the shock is in the violence of the charge; and there are various other considerations which lead one to the view that the manifestations do not make use of quite the same discharge phenomenon in the two cases. The so-called shock excitation, in fact, appears to have its mechanical analogue in the refined escapements of certain clock movements, which are designed to transmit the motion to the pendulum *without shock* and immediately to withdraw so as not to affect the further motion, this proceeding at the natural rate of oscillation. An interesting problem is also presented by claim 9, which relates to the linking of the coherer circuit through a transformer to avoid metallic connection. Now, it would appear easy to circumvent this claim by using an auto-transformer con-

Digitized by Google

nection, which would involve metallic connection that is expressly to be avoided. But since it has already been decided that an auto-transformer and a transformer with two windings are one and the same, it would seem as though we were face to face with the conundrum, "When is a transformer not a transformer?"

London Suburban Railway Electrification.

THE Report of the Departmental Committee on Railway Agreements and Amalgamations issued this week indicates that closer combination and co-operation between railway companies is inevitable in the future, and is on the whole to be welcomed. Although the restriction of undesirable competition is, of course, the main object of the companies, the development of traffic is also one of their aims, and in this connection "through running" is likely to be considered. We do not suppose that the effect produced on "through running" by the electrification of suburban lines in London has yet received full attention, but the question must certainly be faced before long.

ALTHOUGH official confirmation is not yet forthcoming, there is no doubt that the Committee of the East London Railway have decided to electrify the 5 miles of their railway, and the opinion is generally held, as shown by articles in the daily Press, that the continuous-current third-rail system will be adopted. In view of the close connection between the lines of this Company and those of the Metropolitan District and Metropolitan Railways such a decision was to be expected, and the system employed on these last-mentioned railways may, perhaps, be a deciding factor when electrification is considered by other companies. At present the question of interconnection with the single-phase system of the London, Brighton & South Coast Railway has not arisen; but as electrification is extended to other sections of this Company's system the problem of interconnection will become more difficult and the directors of other companies may be placed in a dilemma. Thus, the proposed new electric line from Sutton to Wimbledon will of necessity be operated on the continuous-current system in view of its close connection with the lines of the Metropolitan District Railway, whilst the London & South-Western Railway Company, whose track permits of "through running" with the District Railway at several places, may have difficulty in choosing between the desirability of connecting up with this system and of adopting the single-phase system to prevent isolation from the neighbouring lines of the London, Brighton & South Coast Railway.

Trains de Luxe for an Electric Railway—According to the "Electrical Review and Western Electrician," the Illinois Traction System will shortly place in operation two-car trains composed of a motor car and trailer which will equal in every respect the parlour-car trains on the steam railways. The motor car will be of the library-buffet type and the trailer of the observation-parlour-car type. Both cars will conform to the latest practice in car building. An extra fare will be charged on these trains.

Banquet to Prof. H. E. Armstrong.—As there has been a widespread feeling among Prof. Armstrong's old students that the time is ripe for some collective expression of their indebtedness to him and their appreciation of his services to science and industry during the past quarter of a century, it has been decided to entertain him to a banquet on Saturday evening, the 13th inst. A large committee has been formed to carry out the necessary arrangements, and a number of our leading scientific men will be present as guests. The chairman will be Prof. W. J. Pope, F.R.S., and the vice-chairman Mr. Maurice Solomon. It is hoped that engineering, as well as chemical, old students will respond readily, so as to ensure a successful evening. Applications for tickets should be made not later than the 8th inst., to Mr. F. F. Renwick, Norland House, Avenue-road, Brentwood, Essex.

Electricity in a Composing Room.—According to the "Electrical Review and Western Electrician," the "New York World" is now using electricity in its press and composing rooms, not only for lighting and power but for melting the type metal in the linotype machines. This change has increased the output of the machine by about 20 per cent., while a much better "slug" is obtained. When using the old method, where the heat cannot easily be regulated, the slugs were often found to be imperfect, and had to be replaced. Since electric heating was introduced, however, this has not once been the case. The use of electric heating, too, greatly improves the conditions in the composing room. The electric melting pot is provided with a cover and spout, and is surrounded by a jacket of cast-iron lined with asbestos. A central plunger serves to force the molten metal out of the spout in the customary manner. A number of heating coils supported by insulators are placed in the air-tight space between the melting pot and the jacket. Heating coils of high resistance are placed outside and round the insulating sleeves. The coils are divided so that the heat from the inner group is applied to the main portion of the pot and from the outer group to the spout, so that the greater amount of heat energy is used for melting the metal and a less amount for keeping it in a molten condition. Heat control, which is effected by a thermostat, keeps the metal at the right temperature.

Regulating-Pole Rotary Converters.—The "Electrical World" gives an account of a rotary converter by which a variable ratio between the alternating and direct-current pressures can be obtained without the use of complicated apparatus or wiring. This machine is provided with auxiliary regulating poles, which are so set that each regulating pole adds algebraically its flux to that of a main pole, either increasing or decreasing it, and so increasing or decreasing the direct-current voltage. The current in the regulating pole circuit is varied by means of a rheostat inserted in this circuit. Five of these rotaries, each having a capacity of 1,000 kw., have been installed by the Potomac Power Co. Three of them are used in railway work for supplying current to the Washington Railway & Electric Co. They give a variation in pressure from 515 to 600 volts. By means of these machines any desired subdivision of load between the various sub-stations of the railway company can be obtained, as, by increasing the potential at which the power is supplied by a sub-station, other conditions remaining the same, its load may be increased, while by reducing the potential its load may be diminished. These machines have the usual shunt and series winding on the main poles and a shunt winding on the regulating poles. The series winding on the main pole gives the usual compounding voltage at any pressure to which the machine is adjusted by the rheostat in the regulating pole circuit. The other two converters are used for lighting at a pressure between 240 and 300 volts.

New Wiring Rules (1911).—We have received from the Institution of Electrical Engineers a copy of the new edition of the Wiring Rules which has just been issued. We understand that these new Rules have been adopted by 49 Fire Offices and are accepted as standard practice by 232 supply authorities. The price of the Rules is 6d. per copy (7d. post free), and copies can be obtained from the Secretary of the Institution, or from Messrs. E. & F. N. Spon, 57, Haymarket, S.W. In our next issue we shall refer to the main alterations which have been made since the previous edition of the Rules was published.

A Choice of Systems for Electric Traction.—In the course of discussion on the problem of electrifying the railways in the Boston neighbourhood, Mr. W. S. Murray said, regarding systems of electrification, both the direct and alternating currents had their appropriate spheres of usefulness, but that for trunk lines, long distances and train services requiring large units of power, alternating current was fundamentally necessary. Touching further upon the advantages of alternating-current service, Mr. Murray said that the only power plant the New Haven Co. had was located at Cos Cob, 18 miles north of the Woodlawn junction with the New York Central lines. If direct-current distribution had been used it would have been necessary to instal a sub-station every 6 or 8 miles in order to enable each train to get its full quota of power. It was not clear that the saving in locomotive repairs and fuel paid for the fixed charges on electrification, unless the traffic density was very high. The savings were chiefly in fuel and locomotive repairs, combined with a decided increase in the traffic capacity of the equipment. The actual drop in voltage between Cos Cob and the Harlem River yard, 25·6 miles, at peak load gave a working potential of over 9,000 volts, which enabled the time-table to be maintained. On "Football Day" the output at Cos Cob would rise to 20,000 H.P., and the actual average loss in distribution for the entire day would be only 3 per cent., with a momentary drop of about 14 per cent. at Woodlawn. Confidence could be placed in electrification, but engineers must do what they could to check the popular clamour for it. Mr. Murray showed a large number of lantern slides exhibiting arrangements in construction within the New Haven electric zone, and concluded by briefly describing various features of the Hoosac Tunnel electrification. Two insulators were placed in series in this tunnel, the insulation being sufficient to withstand 300,000 volts. One insulator pair tested after three years' exposure to steam locomotive operation withstood 300,000 volts even when incrusted with soot and dirt, and when cleaned showed practically its initial insulating qualities.

Jubilee of Pacinotti's Machine.—To-day (May 5) is being celebrated as the jubilee of Prof. Antonio Pacinotti's toothed ring dynamo, which may be looked upon somewhat as an inversion of the Gramme ring and the forerunner of the modern toothed-core armature. The machine is described in "Il Nuovo Cimento" of June, 1864, in which Prof. Pacinotti terms the armature a "transversal electro-magnet." The reasons given by the author for adopting this form of armature are as follows:—(1) the current in the armature coils tends to flow, and the driving couple, when it is used as a motor, acts continuously; (2) the circular construction and uniform magnetisation of the parts give regularity of motion; (3) the magnetic changes in the armature core are less rapid; (4) the sparks are more numerous, but of less intensity, since the circuits remain closed. There seems to be some confusion as to when Prof. Pacinotti's article states that he constructed the model in 1860. The date of publication, as mentioned above, is 1864, though some of the reprints made for the Paris Exhibition of 1881 state that the June number of "Il Nuovo Cimento" was published in May, 1864. On the other hand Prof. Vittorio Cavassa, of Genoa, who is Hon. Secretary of the Committee for honouring Prof. Pacinotti, states that 1911, is the exact anniversary. The jubilee is to be celebrated by the issue of a special single number newspaper, containing the address of congratulation (engrossed on vellum) by the Council of the Institution of Electrical Engineers, the only one among many others. In Italy the present year, as the result of these events, is being regarded as the jubilee of the *dynamo*, which mistaken idea is doubtless the result of patriotic zeal.

The following list of Prof. Pacinotti's publications on electro-magnetism beyond the one above mentioned will be of interest to our readers:—

"Ragguagli ed esperimenti sopra una piccola macchina dinamo-elettrica." "Il Nuovo Cimento," 1870.

"Correnti indotte con un circuito magnetico chiuso." "Il Nuovo Cimento," 1872.

"Reso conto di una memoria del Sig. Gaugain sulle correnti indotte sviluppate dalla macchina costruita dal Gramme." "Il Nuovo Cimento," 1873.

"Dell' uso delle elettro-calamite trasversali per la reproduzione elettro-magnetica degleangoli." "Il Nuovo Cimento," 1873.

"Considerazioni sulla elettro-calamita trasversale adoprata come elettro-motore." "Il Nuovo Cimento," 1873.

"Descrizione del Gomitolo elettromagnetico e suo uso nelle macchine magneto-elettriche." "Il Nuovo Cimento," 1874.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. D. Owen contributes an article on "Magnetic Bodies Composed of Non-Magnetic Elements."

"An Electrodynamic Method of Investigating the Interior of the Earth" is described by Dr. H. Löwy.

We give an account of the "Thomas" transmission for motor vehicles. The transmission is partly electrical and partly mechanical. A 2,000-mile road trial of a lorry equipped with this gear is being carried out by the Royal Automobile Club.

At the meeting of the Institution of Electrical Engineers last night a Paper was read by Mr. D. Murray, entitled "Practical Aspects of Printing Telegraphy." The Institution is holding weekly meetings during the present month.

An interesting discussion took place at the meeting last week when Mr. A. M. Taylor read his Paper on "Battery Economics."

A dinner of old Ferrantians was held on Saturday last at the Trocadero Restaurant. Mr. C. P. Sparks was in the chair, and a large company were present to do honour to the guest of the evening, Mr. S. Z. de Ferranti.

Mr. Haydn T. Harrison contributed a Paper entitled "The Ratio of Light to Illumination" at a meeting of the Illuminating Engineering Society last week. A Paper on "Some Notes on the Effect of Wall Papers upon the Illumination of Interiors" was also read by Mr. P. J. Waldram.

The deputation appointed in 1910 by Birmingham Corporation to visit the continent in order to report upon town-planning, &c., has presented an interesting report, which is abstracted in another column.

The Board of Trade have refused to grant a provisional order to Bermondsey (London) Council for the St. Olave district.

Legal.—On Friday Mr. Justice Parker delivered his reserved judgment in the application for the extension of the period of patent No. 11,575/1897, granted to Sir Oliver J. Lodge for wireless telegraphy, and in the result he granted an extension of seven years for certain of the claims in the original specification.

Mr. Justice Swinfen-Eady continues this week the hearing of the action brought by the British Westinghouse Electric & Mfg. Co. against the Electrical Co. to restrain the alleged infringement of the Bremer arc lamp patent.

Companies' Meetings and Reports.—At the meeting of the British Westinghouse Electric & Mfg. Co. the chairman (Mr. J. Annan Bryce) gave an account of the progress made by the Company during the past year, and of the electrical companies in which it is interested.

At the meeting of the Santos Improvement Co., the chairman, Mr. D. M. Fox, gave a sketch of the development of the Company, and supplied particulars of the progress of their electric tramway and lighting branches.

OBITUARY.

We regret to announce the death of Mr. Stephen J. Symonds, secretary and manager of the Farnham Gas and Electricity Co., Ltd.

The death of Mr. W. G. Murrin, electrical contractor, of Wandsworth (London) and Lowestoft is also reported. Mr. Murrin was 55 years of age.

APPOINTMENTS VACANT AND FILLED.

Belfast Tramways & Electricity Committee require a sub-station attendant. Wages £2 per week of seven days. Applications to the city electrical engineer, Mr. T. W. Bloxam, M.I.E.E., electricity works, East Bridge-street, Belfast, by May 9.

A lecturer in applied mathematics is required for the Grey University College, Bloemfontein. Salary £400 per annum. Applications to the High Commissioner for South Africa, 72, Victoria-street, London, S.W., by May 19.

An important firm of electrical engineers require for their London office a junior assistant, with technical training and knowledge of German, for publication work.

Cheltenham Local Higher Education Committee require a director for their technical schools. Salary £220, rising to £250 per annum. Applications to the Clerk to the Governors by May 16.

Mr. Patrick J. Webb, commercial instructor to the County Clare Technical Committee, has been appointed (out of 49 applicants) principal of the City of Galway Tecnhical Institute.

INSTITUTIONS AND SOCIETIES.

Royal Institution.—The annual meeting of this Institution was held on Monday last, the Duke of Northumberland in the chair. The annual report of the Committee of Visitors for the year 1910, testifying to the continued prosperity and efficient management of the Institution, was read and adopted, and the report on the Davy-Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. Thirty-nine new members were elected in 1910, and 61 lectures and 17 evening discourses were delivered. The books and pamphlets presented amounted to about 239 volumes, making with 604 volumes (including periodicals bound) purchased by the managers, a total of 843 volumes added to the library in the year. Thanks were voted to the president, treasurer and the honorary secretary, to the committees of managers and visitors, and to the professors, for their valuable services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year: *President*, the Duke of Northumberland; *Treasurer*, Sir James Crichton-Browne, F.R.S.; *Secretary*, Sir William Crookes, F.R.S.; *Managers*, Mr. J. B. Broun-Morison, Dr. J. M. Bruce, Dr. H. E. Armstrong, F.R.S.; Sir H. B. Buckley, Sir J. W. Barry, Earl Catheart, Dr. D. W. C. Hood, Mr. H. F. Makins, Sir F. Laking, Mr. Alex. C. Ionides, Mr. R. Mond, Dr. R. Messel, the Hon. C. A. Parsons, F.R.S.; Sir J. Stirling and Mr. Alex. Siemens; *Visitors*, Mr. H. Edmunds, Sir F. Fison, Mr. W. A. T. Hallowes, Dr. A. C. Hill, Mr. J. W. Gordon, Mr. H. R. Kempe, Major-Gen. Sir C. Grove, Mr. C. E. Groves, Mr. A. Kirkman Loyd, Mr. F. K. McClean, Sir C. D. Rose, Major P. A. MacMahon, F.R.S., Messrs. W. Stone, E. R. Merton and H. Swithinbank.

Institution of Electrical Engineers.—At the meeting last week the chairman, Mr. W. Duddell, who presided in the absence of Mr. S. Z. de Ferranti, read the list of nominations for the Council, which was given in our last issue. Mr. W. A. Chamen then rose and expressed the pleasure of his friends and himself at Mr. Kingsbury's name again appearing on the list of nominations. It would be remembered, he said, that last year he made an independent nomination which resulted in Mr. Kingsbury not being elected, but he was very pleased to see that Mr. Kingsbury's name was again included. As far as he and his friends were concerned, no opposition would be offered to the present nominations.

Institution of Mechanical Engineers.—The anniversary dinner of this Institution on Thursday last week brought together a distinguished gathering representative of the engineering and other professions. Mr. E. B. Ellington, president, was in the chair, and the company, which numbered about 240, included Dr. T. J. Macnamara, M.P. (Parliamentary Secretary to the Admiralty), the Marquess of Bristol, M.V.O. (President of the Institution of Naval Architects), Sir William White, K.C.B., F.R.S., Mr. F. D. Acland, M.P. (Financial Secretary to the War Office), Lt.-Col. Sir James R. Dunlop Smith, K.C.S.I., Sir William Hall-Jones, K.C.M.G. (High Commissioner of New Zealand), Sir N. J. Moore, K.C.M.G. (Agent-General of Western Australia), Sir John W. Taverner (Agent-General of Victoria), Sir Archibald Geikie, K.C.B. (President of the Royal Society), Sir Charles Owens (General Manager, London & South-Western Railway), Surgeon-Gen. Sir Alfred Keogh, K.C.B., F.R.S. (Rector of the Imperial College of Science and Technology), the Rev. Prof. T. G. Bonney, F.R.S. (President of the British Association), Mr. Alex. Siemens (President of the Institution of Civil Engineers), Mr. S. Z. de Ferranti (President of the Institution of Electrical Engineers), Mr. W. H. Patchell, Mr. F. W. Dyson, F.R.S. (Astronomer Royal), and Coun. E. L. Somers Cocks (Mayor of the City of Westminster).

After the customary loyal toasts had been duly honoured, the president mentioned that His Majesty, King George, had consented to remain, after his accession to the throne, an honorary member of the Institution.

Sir William White proposed the toast of "The Empire." In doing so he emphasised the fact that sea supremacy is vital to the stability of the British Empire, and of no other empire in the world was this the case. He by no means took a despondent view of the growing tendency for people in this country to emigrate to our colonies; in fact, he recommended members to do all they could to encourage young engineers to go to the colonies, so as to relieve the pressure in the home market.

Dr. Macnamara, in responding, gave three reasons for the unique position occupied by the British Empire; these were (1) the Britisher's genius and capacity for self-government, (2) that in the Union Jack they saw a covenant of fair play, liberty and justice, and (3) British pluck and endurance.

Sir William Hall-Jones also responded, and in a spirited speech testified to the loyalty of New Zealand and the determination of all the colonies to stand by the mother country.

The toast of "Our Guests" was then proposed by Mr. J. A. F. Aspinall, and was acknowledged by Prof. T. G. Bonney and Sir Alfred Keogh. The last mentioned speaker stated that he looked forward to the time when there would be a closer connection between the great Societies, such as the Institutions of Civil and Mechanical Engineers, and the colleges, so assisting to direct educational methods in accordance with the requirements of the country.

To the Mayor of Westminster fell the duty of proposing "The Institution of Mechanical Engineers," coupling with it the name of the President. After the latter had responded the proceedings terminated.

National Electric Light Association.—The annual general meeting of this Association will be held in New York from May 29 to June 2. A special train to be known as the "Electric Light Special" will leave Chicago for New York at 2:30 p.m. on May 28.

International Electrotechnical Commission.—The second annual report of this Commission which has just been issued in English and French gives an account of the informal conference which was held at Brussels in August last under the presidency of Mr. Eric Gerard. It is hoped that a full report of the proceedings will be ready shortly. In the present year a full meeting of the Commission is to be held at Turin, the German Committee having kindly foregone their claim to hold it in Berlin as had been originally arranged. A report on the activities of the Congress will be presented at the Pan-American Scientific Congress which is to be held in Washington in October, 1912. As regards the work of the Commission the subject of nomenclature is still being studied with the modification suggested by the German delegate at Brussels, that attention should be confined for the present to a definite and short list of terms dealing with one subject alone, thus avoiding confusion of ideas. Some advance has also been made with the subjects of symbols, rotation of vectors and rating. The Secretary (Mr. C. D. le Maistre) informs us that there are now seventeen countries in which an Electrotechnical Committee has been formed, in the majority of cases with the assistance of their respective Governments. The latest adherents are Holland and Switzerland. Mr. le Maistre has lately returned from visiting the various European Committees where, without exception, the keenest interest is being taken in the work and success of this international movement. In the near future a small international Committee, appointed at a Conference held in Brussels in August, 1910, consisting of Dr. Budde (Germany), Dr. Silvanus Thompson (Great Britain), M. Brunswick (France) and M. Eric Gerard (Belgium), is to meet and discuss the work on nomenclature. This Committee is to prepare a list of terms and definitions dealing with the one subject of electrical machinery, which list is to be ratified by the full meeting of the Commission to be held at Turin at the beginning of September next. Most of the Presidents of the European Committees have signified their intention of being present at Turin, and if the success which attended the Brussels follows the Commission at Turin, as no doubt it will, the work accomplished should certainly be of a very practical and useful nature.

Association of Mining Electrical Engineers.—At the meeting of the West of Scotland Branch of this Association on the 21st ult., at Glasgow, the discussion on Mr. Benson's Paper entitled "Compressed Air versus Electricity in Mines," was continued. (An account of the previous discussion was given in our issue of March 24th).

Mr. A. Anderson (Chairman of the Branch) thought it unfair for Mr. Benson to compare electrical plant, as it was 9 years ago, in its infancy for mining purposes with a rival which had reached manhood

Digitized by Google

The comparison would not hold good to-day. When the only argument that could be advanced in favour of compressed air was that it was able to operate a machine of the reciprocating class, he would refer the author to the discussion on Mr. Kilburn Scott's Paper wherein it was stated that caulkers and rivetters using pneumatic tools every day undoubtedly had their lives shortened. There would always be a difference of opinion as to which system should be used, but on the point of efficiency compressed air would always have a very low efficiency. That was an incontrovertible fact. Thus, during compression 50 per cent. of the work done was carried away as heat by radiation and in the water jackets. (Mr. Anderson explained this by reference to the thermodynamic relations.) Allowing for mechanical losses, an efficiency of 30 per cent. was hardly to be expected. Two or three-stage compressors increased the efficiency of compression by something like 10 to 15 per cent., but the mechanical losses rose so that it was questionable if an overall efficiency of more than 40 to 45 per cent. would ever be obtained.

Mr. D. MARTIN instanced a test he had recently seen carried out. The engines driving the compressors developed 367 I.H.P., while at the working face the power developed by the various tools was approximately 90 H.P.

Mr. W. L. SPENCE said, as confirming the point which Mr. Martin had made, he would consider the figures given just what might be expected. In Cornwall the practice was to allow 30 H.P. at the generating end for every drill for drilling granite.

Mr. ANDERSON said he had had his attention drawn to a compressed air plant at a colliery of considerable magnitude. Immediately the owner discovered that the plant had only an overall efficiency of something like 22 per cent., he had it "scrapped."

Mr. WM. BROWN (Hamilton) said that while there always would be spheres of usefulness for both forms of power in the many intricate operations incidental to mining work, he was still of opinion that electricity was far superior. While it had not been long enough in existence in mines to furnish reliable data as to life and other maintenance charges, still it was simple to transmit electrical energy. The shaft space taken up was for the latter less than 30 per cent. of the air ducts. Then, an 8 in. air pipe in a 20 in. seam meant a lot in the roadways compared with the 1 in. or so for cable. He could recall a case where coal cutting by machinery had to be abandoned also on account of the endless worry due to leaky pipe joints owing to the continual movement of the pavement in the roadways. The use of electric cables would have meant success. They had it on the authority of H.M. Electrical Inspector of Mines that 96 per cent. of the fatal accidents due to electricity were avoidable, so that apprehension on that score could be eliminated with careful attention to installation.

Mr. ANDERSON thought Mr. Brown had opened up a good point in his reference to leaky joints. Was it not the case that the cost of repairs to pipes did not appear as such, as the roadmen looked after them, whereas with electricity the cost of cable repairs was carefully noted.

Mr. BENSON, in reply, said he felt the majority of his critics had unnecessarily laboured the superior efficiency of electrical plant. That he admitted. To ventilate by compressed air never entered his head. It was only in a troubled field, with an extraordinary number of faults and thin seams where compressed air came in useful, also for headings his experience so far proved that the "Liskol" or "Little Hardy" machines were invaluable. As to costs the boiler consumption at his colliery by the addition of air-driven coal-cutters only increased from 0·55d. to 0·75d., less than ½d. per ton of output. That was a point he would like to emphasise.

EDUCATIONAL NOTICES.

Battersea Polytechnic (London, S.W.).—The following courses will be held during the summer term, commencing May 15:—On "Electric Lamps and Illumination," Monday, 7:15 to 8:15; "Fault and Insulation Testing of Electric Mains," Monday, 8:15 to 9:15; "The Electric Railways of London," Wednesday, 7:30 to 9:30. In connection with the course visits will be arranged to sub-stations and depôts.) Fee for each course 2s. 6d. Further particulars from the secretary.

Technological Scholarships.—The West Riding (of Yorkshire) County Council offer technological scholarships, of which not more than four will be of the value of £60 per annum. Applicants must be qualified by residence within the administrative county of the West Riding (excluding the county boroughs). The scholarships will be tenable for one year (combined day and evening courses in connection with industries such as mechanical or electrical engineering, metallurgy, textile work, &c.), and are intended for young persons who have had at least three years' practical experience in workshops or their equivalent. Application forms and particulars from the Educational Department (Technical Branch), County Hall, Wakefield.

Massachusetts Institute of Technology.—The Congress of Technology, which met in Boston on April 10th and 11th, in celebration of the semi-centennial of the signing of the charter of this Institute is reported to have been a pronounced success. The opening session of the Congress commenced with an address by Dr. Maclaurin, President of the Institute, who spoke on "Some Factors in the Institute's Success." "Apart from his appreciation of the value of all sound learning," said Dr. Maclaurin, "William Barton Rogers, the founder and first president of the Institute, saw clearly that the whole controversy as to the relative merits of science and the classics in the field of education missed the mark by placing the emphasis in the wrong place. He understood that when one gets to the root of things in education, the *method* rather than the *subject* is of supreme importance, and his insistence on the value of method in teaching was the cardinal doctrine in his creed and the one that has contributed most to the success of the Institute. The idea is familiar to us all to-day, the idea of *learning by doing*." The second day was given over to the presentation of papers on various aspects of applied science. These papers, which were all given by alumni and members of the faculty, were grouped in six sections and dealt with scientific investigation and control of industrial processes, technological education in its relation to industrial development, administration and management, recent industrial development, public health and sanitation, and architecture respectively. We notice Mr. H. M. Hobart among the contributors of papers, his subject being "The progress of electric propulsion in Great Britain."

Glamorgan C.C. Summer Mining School.—Glamorganshire County Council have arranged courses of instruction to meet the requirements of the new Coal Mines Bill, and a short course of instruction will be given for three weeks during August at the University College, Cardiff.

Instruction will be given in practical surveying, electrical, mechanical and mining engineering (workshop practice), with practical mathematics, metallurgy and chemistry, courses in gas detection, &c. There will also be evening lectures in electrical engineering and a teachers' course in chemistry, geology and physics. Further particulars and forms of application may be obtained from the Chief Education Official, 35, Park-place, Cardiff.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, May 5th (to-day).

DERBY SOCIETY OF ENGINEERS.

7:30 p.m. Meeting at the Mechanics' Institute, Wardwick. Paper on "Electric Steel Furnaces," by Mr. Joh. Härdén.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "New Organic Compounds of Nitrogen," by Prof. M. O. Forster, F.R.S.

MONDAY, May 8th.

GRADUATES' ASSOCIATION OF THE INSTITUTION OF MECHANICAL ENGINEERS.

8 p.m. Meeting at Storey's-gate. Paper on "The Application of Liquid Fuel in Industries," by Mr. O. Wickham.

TUESDAY, May 9th.

ILLUMINATING ENGINEERING SOCIETY.

8 p.m. Meeting at the Royal Society of Arts, John-street, Adelphi. Annual General Meeting.

WEDNESDAY, May 10th.

JUNIOR INSTITUTION OF ENGINEERS.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment. Paper: "Notes on Illumination by Gas and Electricity," by Mr. F. J. Hawkins.

THURSDAY, May 11th.

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Lecture on "The Optical Properties of Metallic Vapours," by Prof. R. W. Wood. Tyndall Lecture III.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at Victoria Embankment, W.C. Paper on "The Driving of Winding Engines by Induction Motors," by Mr. H. J. S. Heather.

FRIDAY, May 12th.

PHYSICAL SOCIETY OF LONDON.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "Stream Lines Past the Elliptic Cylinder and Magnetic Interpretation," by Sir George Greenhill, F.R.S., and Col. R. W. Hippisley, R.E.; "The Method of Constant Rate of Change of Flux as a Standard for Determining Magnetisation Curves of Iron," by Messrs. J. T. Morris and T. H. Langford; and "Demonstration of an Electric Thermo-Regulator," by Prof. H. L. Callendar, F.R.S.

Digitized by Google

THE VOLTAGE BETWEEN COMMUTATOR SEGMENTS.*

BY THEODORE HOOCK.

Summary.—The author shows that the maximum voltage between commutator segments depends on the saturation of the magnetic circuit, and he points out how it increases, in the case of a motor, when the speed is raised by shunt regulation.

It is very important to know the magnitude of the maximum pressure between the commutator segments, in order to design a good machine. In machines without commutating poles, a maximum voltage between segments of 30 to 35 volts will cause sparks to appear at the brushes, while if the commutator is in a bad condition, 40 volts may cause an arc or flash-over. With 500-volt traction motors without commutating poles, the pressure between segments usually reaches the upper limit (30 to 35 volts), when so-called harmless sparks are seen, but in case of sudden voltage variations due to short-circuits, &c., a flash-over occurs between the brushes and frame, due to the momentary increase in the segment-pressure. This may also happen with commutating-pole machines, on account of the small air-gap and high specific armature loading (AS).

Practical values of the pressure between segments lie between 12 and 25 volts, in any case lower than 30 to 35 volts. With a maximum voltage of 50 volts, even with sparkless running and a clean commutator, there is a tendency to flash over.

1. *Open-Circuit Field.*—The pressure between adjacent segments at any point is a function of the speed of rotation of the coils between the two segments and the resultant field at that point. If E=induced E.M.F., $2p$=number of poles, $2a$=number of parallel paths in armature, k=number of segments, the mean pressure between segments on open-circuit is (Fig. 1, curve a) :—

$$e_{mean} = E \cdot 2p/k. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

This assumes that the field-curve is rectangular, so that the pressure varies from $+e$ to $-e$ at the neutral point. Assuming the field-

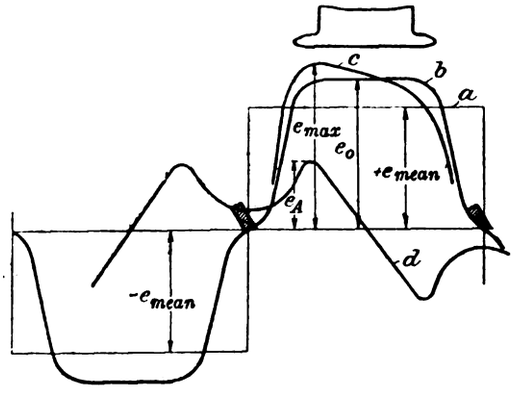

FIG. 1.

a=Ideal field curve ; b=Actual field curve on open circuit ; c=Field curve on load ; d=Armature field.

curve is sinusoidal, the value 2, in equation (1), becomes π—that is, e_0 is 1·57 times as large.† Measurements on standard machines give values about 45 per cent. higher than equation (1), and 8 per cent. smaller than by the substitution of π for 2.

Introducing a factor, which varies between 2·7 and 2·9 according to the ratio of pole-arc to pole-pitch and to the shape of the field, we obtain the more accurate equation (Fig. 1, curve b) :—

$$e_0 = \frac{(2{\cdot}7 \text{ to } 2{\cdot}9)a}{k} \cdot \frac{E\,p}{a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

We also obtain the same result from the particulars of the machine. If B_i=density in the air-gap, l_i=ideal length of armature, w=turns per segment, we have

$$e_0 = 2\,p/a\ B_i \cdot v \cdot l_i \cdot w \cdot 10^{-8}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

By means of this equation the distribution of the density in the gap can be obtained. It must be noticed that this only gives the actual field-strength with full-pitched lap windings ; with series windings only a mean value over all the poles is obtained. This, however, has very little effect on the maximum pressure between segments.

2. *Armature Field.*—If the brushes are kept in the neutral position, a very small excitation of the main poles suffices to send full-load current through the armature at normal speed. In some cases even, remanence in the field system will be enough to supply many times the full-load current on short-circuit. If it is desired to test the machine with full-load current, either the speed must be reduced, or resistances must be connected in series with the armature, or the remanence must be eliminated. Shifting the brushes also has the same effect.

Curve d in Fig. 1 represents the armature field. Its zero value coincides with the centre of the pole. On each side it follows a straight line and reaches its maximum at the pole-tips. Since the armature field follows a straight line only with a concentric pole-arc, we will only consider this case.

We are now only interested in the maximum field strength and the pressure between segments on short-circuit, which is proportional to the field-strength.

The maximum density in the gap under the pole-tip at short-circuit is :*—

$$B_A = \frac{b_i \cdot AS}{1{\cdot}6 \cdot k_1 \cdot \delta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and the maximum pressure between segments at short-circuit

$$e_A = 2p/a.\ B_A \cdot l_i \cdot w \cdot v \cdot 10^{-8}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where b = ideal pole-arc,
AS = armature ampere-conductors per centimetre,
k_1 = factor taking the slot openings into account,
δ = air-gap.

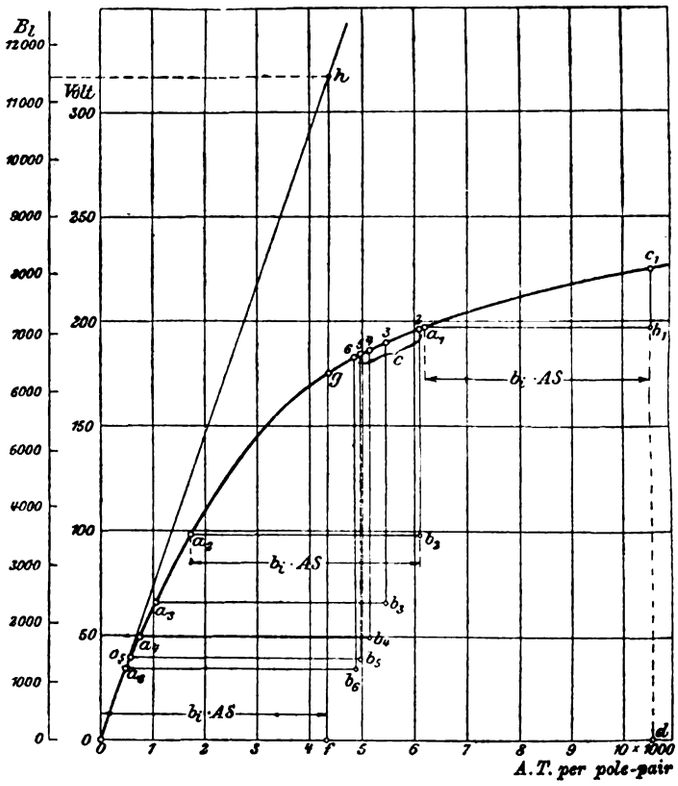

FIG. 2.—OPEN CIRCUIT CHARACTERISTIC OF A MOTOR WITH A SPEED VARIATION OF 1:6 BY SHUNT REGULATION.

The calculation of e_A is of importance for boosters, and all machines which work without excitation or with weak fields and high armature reaction. It is also useful for testing standard machines on short-circuit.

If the density in the gap is found from equation (4) to be

$$B_A < 4{,}000 \text{ to } 5{,}000,$$

so that the density in the teeth

$$B_z < 12{,}000 \text{ to } 15{,}000,$$

equation (5) can be used for e_A without correcting for saturation.

If, however, the iron is saturated, the open-circuit characteristic of the machine can be used with sufficient accuracy for calculating e_A. Assuming that we find from equation (4) that B_A=11,400, there is no longer proportionality between the density in the gap and the ampere-turns.

In Fig. 2 we find O—f ampere-turns on the main field for B=11,400, or, employing the armature field, we have, for an ideal gap-density B_A=11,400 and b_i. AS armature ampere-turns, an actual gap-density of 11,400 $\frac{gf}{hf}$; or, in other words, the pressure be-

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

tween segments with full-load short-circuit current equals, from equation (5),

$$e_{A1/1}=2p/a\ 11{,}400\frac{gf}{hf}.\ l_i\ .\ v\ .\ w\ .\ 10^{-8}.$$

3. *The Resultant Field.*—If the machine is loaded, the resultant field-curve takes the shape shown by curve *c* in Fig. 1. Since we start with normal excitation on the main poles, we cannot neglect the effect of saturation.

The armature teeth, air-gap, pole-shoes and armature core are traversed by both the main and armature fields, and we can calculate the field-curve on load by superposing them.* As already mentioned, the open-circuit characteristic suffices for this. In Fig. 2, the point *a* represents the E.M.F. on full-load. Drawing now the armature ampere-turns b_1AS to the right from *a*, the ratio of the ordinates $\frac{cd}{ab}$ gives the increase of pressure between segments on full-load. An example will illustrate this.

In motors having a speed-variation of 1:4 or 1:6, the main ampere-turns are only a fraction of the armature ampere-turns at the higher speeds. We can, therefore, neglect the effect of the main field on the armature field and calculate the pressure between segments as for a machine on short-circuit.

Consider now a motor having a speed variation of 200 to 1,200 revs. per min., of which the open-circuit characteristic is shown in Fig. 2. We are given the following data :—

$A=205$, $b_i=21{\cdot}5$ cm., $v=0{\cdot}215\ n$, $\delta=2$ mm., $l_i=22$ cm., $k=147$ segments, E=220−23=197 volts, $w=3$ per segment.

At full-load and $n=1{,}200$, $v=25{\cdot}8$ m/sec., and we have, from equation (4), for the ideal gap-density,

$$B_A=\frac{21{\cdot}5\ .\ 205}{1{\cdot}6\ .\ 1{\cdot}2\ .\ 0{\cdot}2}=11{,}400.$$

We now find the point *h* in Fig. 2 and from it the point *g* on the curve, which gives an actual gap-density of $B_{AW}=6{,}300$. Placing this value in equation (5), we obtain the maximum pressure between segments at full-load and 1,200 revs. per min. to be

$$e_6=.\ 2\frac{2}{1}.\ 6{,}300\ .\ 25{\cdot}8\ .\ 3{\cdot}22\ .\ 10^{-8}=43\text{ volts.}$$

Hence, we have :—

At full-load and $n=1{,}000$

$$e_5=\frac{1{,}000}{1{,}200}43=35{\cdot}9\text{ volts,}$$

At full-load and $n=800$,

$$e_4=\frac{800}{1{,}200}43=28{\cdot}7\text{ volts,}$$

At full-load and $n=600$,

$$e_3=\frac{600}{1{,}200}43=21{\cdot}5\text{ volts,}$$

At full-load and $n=400$,

$$e_2=\frac{400}{1{,}200}43=14{\cdot}3\text{ volts.}$$

It is clear from this how large an increase can be obtained in the pressure between adjacent segments by weakening the field. The pressure at no-load is about 8 volts, so that we have 1·8, 2·75, 3·65, 4·55 times this value on full load.

Now we have not taken the main field into account here, but the following calculation will show that this omission introduces no appreciable error.

At full-load and $n=200$, let a_1 (Fig. 2) represent the E.M.F. Then b_1 is increased in the ratio $dc_1 : db_1$, as shown above, and we have

$$e_1=\frac{2{\cdot}9\ .\ 2\ .\ 197}{147}\frac{dc_1}{db_1}=8{\cdot}9\text{ volts.}$$

The speed is doubled, the gap-density is halved, and, therefore, from Fig. 2 we find a_2 in Fig. 2 at a point where

$$B=\tfrac{1}{2}\ .\ 7{,}100=3{,}550.$$

Setting again the armature ampere-turns, we obtain the maximum pressure between segments at 400 revs. per min. :—

$$e_2=7{\cdot}8\frac{\overline{oc_2}}{\overline{ob_2}}=15{\cdot}5\text{ volts.}$$

Similarly :—

At 600 revs. per min., $e_3=7{\cdot}8\dfrac{\overline{oc_3}}{\overline{ob_3}}=22{\cdot}6$ volts.

At 800 revs. per min., $e_4=7{\cdot}8\dfrac{\overline{oc_4}}{\overline{ob_4}}=29{\cdot}2$ volts.

At 1,000 revs. per min., $e_5=7{\cdot}8\dfrac{\overline{oc_5}}{\overline{ob_5}}=36{\cdot}3$ volts.

At 1,200 revs. per min., $e_6=7{\cdot}8\dfrac{\overline{oc_6}}{\overline{ob_6}}=43{\cdot}3$ volts.

These are practically the same values as those obtained by the previous method.

As a general rule, therefore, it is sufficient to calculate the gap-density for the top speed, correct it once for all and then put the maximum pressure between segments proportional to the speed.

For traction motors with commutating poles several firms make use of shunt regulation for varying the speed.

The use of compensating windings makes it possible to reduce the field-distortion on load to a minimum. They are, therefore, employed when high pressures between the segments are unavoidable, or when heavy rushes of current or sudden high overloads are to be expected. If it were possible to make the compensating ampere-turns exactly equal to the armature ampere-turns under the pole, no increase in the pressure between segments would take place, but since this is not possible, the distortion varies between 5 and 10 per cent. on load, either positive or negative.

It has been assumed in all the above calculations, that the brushes remained in the neutral line; shifting them increases the pressure between segments. The position of maximum pressure is affected by the dimensions of the pole-tips, the breadth of the pole and the strength of the excitation. The maximum usually occurs under one corner of the pole. Strongly saturated pole-tips are also desirable, since they considerably reduce the maximum pressure.

It is not possible to calculate the field-distortion accurately, not even with a theoretically correct method, because the magnetic reluctances can only be determined at low saturations. Even the arrangement and dimension of the field-coils affect the result. If we are given measurements for one shape of pole, good agreement with the calculations can be obtained.

* Arnold, "Gleichstrommaschine."

SURGING OF SYNCHRONOUS MACHINES.*

BY E. J. BERG.

Surging, or what is often called hunting of synchronous machines, resulting in pulsations of current and voltage, is one of the most perplexing and annoying of the phenomena with which the central station engineer meets. It is always associated with pulsation in speed and in power. The pulsations may be caused by the lack of uniformity of the speed of the prime mover, or by the electrical operation of the machines, or by both. With the limitation of speed variation of prime movers imposed by electrical manufacturers, there is little likelihood that the cause of the hunting is the prime mover if the governor mechanism and its dashpot is of good construction. It is more likely to be due to insufficient dampening of the magnetic circuit of the machines or to too much dampening, or in general to the electrical constants of the circuit. The theory of this phenomenon is fairly well understood, at least in so far as it applies to ideal machines.

The author takes the case of an alternator supplying a synchronous motor, and shows that there is a critical minimum value of reactance, corresponding to the resistance between the generators and the motor, which minimum value depends upon the amount of speed-variation of the alternator armature. It is given by $r \tan a$, a being the angular displacement. It is evident, therefore that the required reactance for stability is practically insignificant—far less than that which is found in any commercial machine. Thus, there can be no difficulties by such small speed variations.

The trouble is most often traced to defective design of the governing mechanism of the prime mover or to characteristics of the synchronous machines which do not appear in text-books or ideal machines. With sudden change in excitation the flux changes more slowly than the excitation on account of the effect of eddy-currents. Depending upon the field construction, the time required to build up the magnetism in the field may vary from a fraction of a second in laminated structures to 10 seconds or even longer in structures of solid steel, or in structures of laminated steel with embedded squirrel-cage windings. The flux produced by the armature M.M.F. would appear simultaneously with the current if the magnetic structure were perfectly laminated, and if the field-winding was open-circuited. In reality the structure is seldom so well laminated that no eddies occur, and the field-winding is always excited—that is, closed upon itself (through the exciter); thus, at the best, the flux appears later than the current causing it, and much later if the field poles have squirrel-cage winding. Thus, while two machines may have the same electrical constants, the same armature resistance and reactance, the same excitation of full load and no-load, the same armature reaction, their characteristics at the instant of change of load may be very different.

In calculations of generator characteristics, the term "synchronous reactance" is usually introduced; it means a fictitious

* Abstract of a Paper read before the Western Society of Engineers.

Digitized by Google

reactance which gives the same effect as that of the self-induction and armature-reaction combined. This term is justified in an ideal generator having uniform magnetic reluctance in all positions of the armature, and having a magnetic structure which permits the flux to change at once with the change of M.M.F. Obviously, in a machine with good mutual induction between field and armature-winding, a machine with squirrel-cage winding, this condition is not fulfilled. The result is that if, for instance, full-load is suddenly thrown on the machines of the two types, in the first type the machine will take its load when the speed has dropped so that the angle between induced E.M.F. and terminal E.M.F. is, say, 15 deg., whereas, in the latter type it may be only 1 deg.

The same applies to the synchronous motor, but in this case the different characteristics play an important part in the stability of operation. The author considers the behaviour of the two types of motors when operated from a large generating station over a non-inductive line, and shows that for a particular case whilst the motor with excessively damped field-circuit can be loaded up to the same output as the first type if the load increases slowly, it will shut down immediately if more than about 20 per cent. of full load is suddenly thrown on. He concludes that such a motor should have some external reactance if it is to be able to carry pulsating load, and that whilst both types of motors are by theory less stable the greater the resistance, the second type is far more sensitive. A motor of the first type—that is, a motor with laminated field—while often operating satisfactorily may, however, be unstable on account of excessive reactance.

Every synchronous machine has a natural period—that is, a period at which it will oscillate when adjusting itself from one load to another. The frequency is practically proportional to the square root of the field-excitation and inversely proportional to the square root of the moment of inertia. While such oscillations always take place with changes of load, they are usually of little importance, since they cover a small phase angle only. If, however, the synchronous motor is supplied with power from an alternator whose speed for some reason or other pulsates at the same rate as the natural period of the motor, then a condition of resonance takes place and the machines cannot operate satisfactorily in parallel. In such case, the remedy is obviously to change the natural period, which can be done by increasing or decreasing the moment of inertia, or by changing the air-gap and thereby the excitation.

In general, it may be concluded, as far as the electrical side of the surging problem is concerned, it can be solved by one or more of the following alternatives: (1) Reduce the ohmic resistance between the machines. (2) Exclude all external reactances and put field-damping devices on machines of laminated fields and quick magnetic circuit, especially if the synchronous impedance is great—that is, if they, as generators, have poor regulation. (3) Add extra reactance in high-speed machines having good mutual induction between field and armature and sluggish magnetic circuit. (4) Change the natural period by change of air-gap or addition of flywheel, &c.

While thus something can be done by changing the electrical constants, it is but seldom that this is necessary. Ninety-five cases of every hundred can be traced back to some mechanical defect of the prime mover. Usually the governor is too sensitive, or there is some play in the various links connecting the governor proper with the steam-admitting valves. Sometimes, by the very nature of the drive, difficulties can be anticipated; for instance, when several generators or motors are belted to the same shafting, when it is always possible that the pulleys might be of slightly different diameters or the belts of greatly different quality.

In the case of hunting between direct-connected engine-driven units, it is easily ascertained if the governing mechanism is at fault by disconnecting it and operating by throttling. Should hunting still persist, it would seem necessary to resort to some of the three electrical remedies suggested, and, if these are impractical, to add some flywheel capacity. In conclusion, it is believed that any surging difficulty can be solved by the remedies suggested; indeed, with practical experience of a large number of cases, the writer has never met a case which could not be disposed of by them.

DISCUSSION.

Mr. P. JUNKERSFELD said some trouble occurred in Chicago with motor generators on the 25-cycle system. When the first motor generators were installed, the source of power was principally from a large double current generator, which, however, carried some elevated railway load, resulting in fluctuation of speed of the engine. The hunting troubles were minimised, although not entirely remedied, by anti-hunting devices on the pole pieces. A year or two later, by squirrel-cage windings on the motor the troubles were further reduced. They, however, had all disappeared since the advent of the steam turbine.

Mr. E. E. DUDLEY thought that in most cases much better regulation could be obtained with a sensitive governor if the sensitiveness could be regulated in such a way as to prevent the governor over-travelling. He thoroughly agreed with the author on lost motion in the governor connections. Those who had not had a great deal of experience with water-wheel and engine-driven machines could not realise how very small an amount of lost motion could be felt.

Mr. D. W. ROPER referred to early single-phase central station experience. He found that by connecting their monocyclic windings (supplementary or "teaser" windings connected to the middle point of the main winding and used for supplying three-phase motors) two machines which exhibited no tendency whatever when operating single-phase to keep in step ran in parallel very well. Again, a 1,000 kw. rotary which gave a fluctuating voltage when supplied from engine-driven units, ran very smoothly when the Fisk-street (Chicago) turbine plant was used.

Mr. W. B. JACKSON did not remember having come in contact with a case of surging of alternators where some sort of device had not been worked out to make parallel operation possible, and asked if there were any cases that had not been cured.

Mr. C. W. CRAVENS asked as to cross currents in the neutral.

Dr. BERG, in reply, said that triple frequency currents were of no consequence in connection with hunting. Experience showed that the very sensitive governor was no good as far as parallel operation was concerned; and if it were practical to operate machines on the throttle there would probably be little or no trouble in parallel operation. It was necessary to have a powerful dashpot, so that the governor was almost inoperative except in emergency. It was now relatively easy to cure hunting, but this was not the case 18 years ago.

ILLUMINATING ENGINEERING SOCIETY.

At the meeting of this Society held last week at the Royal Society of Arts, two Papers of considerable interest were read. The first was by Mr. Haydn T. Harrison, and was entitled

"The Ratio of Light to Illumination."

The author considers light as that which causes illumination, whether that illumination is visible or not. He agrees, for instance, with Mr. Trotter's definition of illumination as depending simply on the quantity of light falling upon a surface, and that it has nothing to do with the colour or reflecting value of that surface. Therefore, it would be, strictly speaking, inaccurate to state that an instrument such as the Holophane Lumeter indicated the illumination, except when it was pointed at a white screen of similar material to the screen in the instrument itself.

To demonstrate his point the author has carried out the following experiments with his "Universal" photometer, as made by Elliott Bros. By replacing the standard comparison screen in the instrument by the various tinted wall-papers which Mr. Waldram used in his experiments (referred to in the following Paper) the increased illumination necessary in order that the rays reflected from such wall-papers should have the same effect on the eye as when a white paper of similar surface to the photometer screen was used could be ascertained very accurately. The results are as follows:—

Colour.	Increased illumination necessary.
Bright red	3·5 times
Dull cardinal red	6·5 ,,
Medium blue	4·8 ,,
Light blue	3·2 ,,
Dark green	7·0 ,,
Light green	2·2 ,,

Another interesting point that these tests proved was that the angle of incidence of the light rays closely followed the cosine law over the greater part of the angular movement, despite the fact that the surfaces of these wall-papers were far from plain.

The next experiment was to ascertain the value of the light reflected from the area of these papers compared with that from white blotting paper, and though these tests were made under very different conditions and very roughly, they coroborated the figures given above, thus proving that an instrument of the Holophane Lumeter class measures correctly the irregular reflecting value of a surface.

Mr. Trotter once said: "Such terms as illumination, brilliancy brightness, intensity, and luminosity are generally employed by different writers to express different ideas, and are often used in a confused, vague way." This, unfortunately, is still true to-day, so that it is difficult to fix definitely a unit which accurately describes reflecting value. The author doubts whether a better word than "luminosity" could be chosen. Sir William Abney describes luminosity as brightness resulting from illumination, which is exactly what the Holophane Lumeter measures. But in this case are we to regard "luminosity" as denoting luminous flux per unit area so that it would be expressed, say, in lumens per square inch? Or as denoting candle-power per unit of area?

Digitized by Google

With regard to the other terms, personally I use them in the following sense:—

Light.—The emanations from a light source.

Illumination.—The extent to which anything is illuminated; foot-candles.

Brilliancy.—Refers to primary light source and is candle-power divided by area.

Intrinsic Brilliancy.—Candle-power per unit surface (square centimetre).

Brightness and Intrinsic Brightness.—Same as brilliancy.

Luminosity or Luminous Intensity.—Same as brilliancy, but applied to secondary sources of light.

I only put the above table forward as suggestive, and would like to see the terms "brilliancy" and "brightness" always applied to primary light sources, as considerable confusion, which is now caused by their indiscriminate use, would be obviated. For example, many people talk about a bright light, and this, under the above classification, would be correct; but for an artist to talk about a bright colour would be incorrect.

Luminosity or luminous intensity is used as applied to indirect or secondary sources of light, the value of these sources could be stated in lumens instead of candle-power, which would simplify matters considerably. For example, if we could state that any given part of a room was illuminated to a certain degree in foot-candles by direct light from a source, plus so many lumens in the form of indirect illumination, we should know at once the relative reflecting value of the surroundings of the light source, and also the likely density of the shadows. This would not be a difficult thing to measure, as, excluding the direct light from the measuring surface, we get the illumination due to the lumens (indirect lighting) only.

The measurement of the illumination derived from all sources is, of course, an easy matter, such instruments as the Trotter photometer, Holophane Lumeter with subsidiary screen, and several others being available for the purpose; but to ascertain the light value of the original source of such illumination is a very different thing.

The only satisfactory method is either to eliminate all reflecting surfaces or to remove the lamps to the test-room. In either case the question presents itself as to what is the light source—is it the lamp only, or the lamp plus the globes and reflectors?

It must be borne in mind that globes and reflectors only enhance the lamp's value as a light source for the purpose of giving direct illumination, and often depreciate its value from the point of view of the reflected illumination derived from the surrounding objects. Therefore, the value of the naked lamp alone must be known, and this is, of course, easy to ascertain by the usual photometric methods. The value of such a lamp plus globes or reflectors is a more complicated matter, owing to the area of the light source being increased, and thus interfering with the square law of photometry. Under these circumstances, unless means are available for obtaining the polar curve of lighting, the only way to ascertain the illuminating value of a light source, including reflector, &c., is by ascertaining the illumination results. For this reason I would suggest that all makers of lamps who wish the apparatus supplied by them to be used to the best advantage should accurately state the candle-power developed at various angles.

This naturally leads to the consideration of the relative merits of lights with reflectors or globes which increase the illumination in the direction required, versus unprotected lights from which good illumination is obtained by using the walls or ceiling as reflectors. It is obvious that, as regards efficiency, the use of reflectors will generally have the advantage. Take, for example, a room with white ceiling and walls. The upper hemispherical rays are reflected back into the room and usefully increase the illumination, but, on the other hand, a reflector placed directly over the lamp, provided it reflects all the upper hemispherical rays, will even more efficiently project them on to the remainder of the room where illumination is required, but will leave the upper part of the room in comparative darkness. In the case of a room which has not a white ceiling and walls, while the efficiency of a reflector will be comparatively higher, what is even more important, will remain constant owing to the reflector can be cleaned more often than it is convenient to whitewash the ceiling and walls of a room. But the physiological (light effect is different, because the illumination is derived from a single source, while in the other case it emanates from all directions. A person entering a room with light-coloured ceiling and walls will often state that it is better illuminated than a similar room where the surroundings are dark coloured. Nevertheless, the illumination in the latter case may be better than in the former, and while the physiological effect would eventually prove more generally satisfactory as the high luminosity of the surroundings would tend to close the iris, thus producing a trying effect on the optic nerve, an attempt to work is made under those conditions. Nature tones down the luminosity of surroundings as the brilliancy of the sunlight increases by providing them with a covering of green which is restful to the eye.

Artists have learnt that in order to depict high illumination they must have strong contrasts, such as the deep shadows provided by Nature, and I think in this respect they teach illuminating engineers a lesson. Shadowless illumination is always depressing, just as a day when the sun is obscured by clouds is depressing; and I think it would be wise to deliberate carefully before any system of shadowless illumination is adopted, and to remember that the object of all illumination is to produce an effect by which the outlines of objects are easily seen; which result is greatly assisted by the effect of light and shade.

Mr. P. J. WALDRAM then read a Paper entitled

"Some Notes on the Effect of Wall Papers on Illumination."

When one considers the enormous development of the gas and electric lighting industries throughout the world, it seems strange that few exact rules should exist which would enable any given degree of illumination to be predetermined from illuminating units of given candle-power distribution. It is no exaggeration to say that very few experts could say whether the factor of reflection and counter-reflection in any given case will increase the total illumination by 10 per cent., by 50 per cent., or by 100 per cent. A not unusual way out of the difficulty is to calculate the direct flux only, leaving any increase due to reflection to make up for subsequent deterioration in lamps.

It is, moreover, a direct temptation, in cases where economy is of importance, to specify shades which tend to concentrate the rays of light into a given specified working plane, leaving the walls and ceilings objectionally dark, and leaving the working plane under the disadvantage of a strong undiffused light, very liable to cause shadows and glare from glazed surfaces. The secret of all successful artificial illumination is to approximate as closely as we can to those conditions of daylight under which our eyes have developed; and the property which all artificial illuminants lack is diffusionn.

Our eyes accept without protest huge differences in range of daylight because it is so perfectly diffused by the enormous depth of atmosphere through which it must pass; but a difference of even two or three foot-candles in artificial illumination will cause considerable inconvenience.

Optically, it would appear that the correct policy is to utilise as fully as possible the reflecting and diffusing properties of walls and ceilings, and to afford relief from trying uniformity by the use of coloured surfaces, in positions where they will catch the eye without unduly reducing the efficiency of the installation.

What is expected of any scheme of artificial illumination is as follows:—

(1.) That the working or table plane of the room shall receive an equable light, as much diffused as possible, sufficient for the purposes for which the room is to be used without being excessive.

(2.) That the walls and ceilings should receive and reflect such an amount of light that they appear to be neither too glaring nor too dull, with all essential architectural features brought into sufficient prominence.

Up to the present it has been customary to neglect more or less the wall and ceiling illumination and to consider the working plane illumination as being a criterion of the whole. This is not only wrong, it is injudicious. The walls are what practically every one unconsciously judges by. According as they are bright or dull, warm in tint or cold, so, rightly or wrongly, the illumination of the room is popularly classed. The light reflected by the walls and ceilings has a psychological effect upon those who use, judge, and pay for it, which neither the architect nor the lighting expert can afford to disregard. Commercially, too, the reflected light from walls and ceilings is important, and it ought to be understood that a large proportion of light which falls upon walls and ceilings of poor reflecting capacity is absorbed permanently, and represents money thrown away without any result.

A dark-walled room with a dull ceiling will not only always look dull but also will actually be decidedly more expensive to light than a similar interior possessed of better reflecting surfaces. Light walls not only impress the user, they also assist very materially to illuminate the ceilings, the table planes, and themselves. Considering that rooms can be illuminated entirely by reflected light from the ceiling and walls with an almost entire absence of shadow, it is obvious that ignorance of the value of such an important factor is almost inexcusable. There is a need for recognised standards of surface brightness which will be satisfactory for different classes of interiors, and the author ventures to suggest that the Council should take steps to establish such standards.

The predetermination of interior illumination is, at first sight, by no means an easy problem. But however complicated reflection

Digitized by Google

may be. its total *effect* at any point can be ascertained by simply screening off any direct rays previously incident on that point from the light source. If such results were obtained, averaged, and recorded for a sufficiently large number of interiors and conditions, there would be little difficulty in determining, at least approximately, what reflected illumination might be expected from any given flux of direct light on walls and ceilings of different colours and textures.

The author suggests that the reflection co-efficient for any paper, colour, or texture can be ascertained with sufficient accuracy for all practical purposes by measuring its apparent surface brightness in a direction normal to its surface, as compared with that of white blotting paper, a Holophane Lumeter standard card, or any other suitable standard under the same illumination.

Candle-power curves of lamps and shades are not used at the present time to anything like the extent which they ought to be, and to which they would be were it possible for the lighting expert to obtain them readily for any combination of lamp and shade. It is, however, no small matter to place a lamp and its shade upon a photometer bench and test it at all angles ; and if it were possible to obtain a fully accurate curve from a lamp and shade either in actual use or fixed temporarily to a point, doubtless they would be used more largely. The author suggests the following method as being simple and sufficiently accurate for practical purposes.

To one end of a light wood lath is fixed a vertical bent plate of tin blackened and marked in degrees and carrying a plumb bob so that the angle with the horizon at which the rod is being held can be at once read off. Part of the tin plate is bent at right angles to the direction of the lath, and a plate of known whiteness—white blotting paper or a Lumeter test-plate—is attached by means of a rubber band. A blackened brown paper screen is held or hung behind the lamp and shade to be tested ; the lath is held with the point just touching the lamp. The illumination in foot-candles produced on the test-plate is then read, with the lath held at different angles. This illumination (except in a blackened room) is produced partly by the lamp and partly by reflection from surroundings, or even by other lamps. The rays coming from the lamp alone are isolated from the extraneous light, as follows: A small black screen of such a size as just to screen all the rays from the lamp and shade, but nothing else, is held in a notch in the lath, and a reading taken under these conditions represents the extraneous light only. The difference between the two represents the direct rays from the lamp and shade only. The net foot-candle readings divided by the square of the length of the lath used give the required candle-power at various angles. The method gives curves which approximate very closely to those obtained in the laboratory, and it also enables curves to be measured for gas mantles, oil lamps, wax candles, &c., which are very difficult to obtain in any other way.

A very exhaustive series of tests on the increase in flux due to reflection was carried out by Sharp and Millar in America last year in a room about 12 ft. by 12 ft. by 10 ft. high, with a powerful pendant lamp near the ceiling. The walls were "greyish-white," the ceiling white, and the floor brown linoleum. Briefly summarised the results are as follows : the lamp used directed an average flux of 1·20 foot-candles on to the ceiling, 2·50 foot-candles on to the walls, and 1·25 foot-candles on to a table plane 3 ft. from the floor. It was found that the total effect of reflection and counter-reflection from walls and ceilings *under these conditions* was equivalent to an average secondary flux of 1·90 foot-candles on the walls and 0·65 foot-candles on the ceiling, whilst the illumination on the table plane was doubled to 2·5 foot-candles.

This test gives only the results for one size of room, one scheme of colour, and one scheme of lighting. What we require are more numerous (if less detailed) results obtained in a number of rooms of different sizes with different schemes of colour and with varying proportions of light thrown upon walls, ceilings, and floor respectively by means of light units at varying heights with various shades.

The author is making a number of such tests of different rooms. The method adopted is to divide the floor, walls and ceilings into a number of equal rectangles. The candle-power distribution curves of the lamps having been measured as before described, readings were then taken with an illumination photometer of the illumination received by a detached test-plate in the centre of each rectangle. Then another series of readings was taken with a small black screen placed about half-way between the test-plate and each lamp, so as just to cut out the direct lamp rays whilst obliterating as little as possible of the light reflected from the ceiling. This second test of readings isolates the increase due to all reflections and counter-reflections, and the difference between the sets of readings should equal the direct flux as calculated from the candle-power curves.

A room about 19 ft. by 12 ft. 3 in. by 10 ft., papered with very dull red paper possessing a co-efficient of reflection of only about 11½ per cent., was temporarily fitted with two 35-watt Mazda pendant lamps and tested with different Holophane shades varying the incidence of the light rays. The walls were then altered from such an approximately worst condition to an approximately best by covering them temporarily with white lining paper with a co-efficient of reflection of 100 per cent., and similar readings were taken. It is proposed to compare the results thus obtained with a series of tests which, I understand, is now being made by Holophane, Ltd., in a smaller room hung with a series of different coloured papers. The Holophane tests should be of great value when completed.' As far as the author's results have been carried it would appear that under average conditions the increase of flux of illumination on walls by reflection tends to vary somewhere from between 50 per cent. and 70 per cent. with white wall paper down to between 20 per cent. and 30 per cent. with very dark papers. The increase of flux of illumination on white ceilings appears to be in about the same proportion as on the wall papers to which they are adjacent. The increased illumination on table planes in foot-candles appears to be about a mean between the increases in foot-candles of the flux on the walls and on the ceiling.

DISCUSSION.

Mr. A. P. TROTTER, in opening the discussion on the two papers, referred to the formula for obtaining the increase in illumination due to reflections and counter-reflections. The illumination was increased in the ratio o 1/(1—coefficient of reflection). He also suggested tests on a small model room with, say, a ½ c.p. lamp and various samples of wall paper, carpets &c.

Mr. JUSTUS ECK thought Mr Harrison's definitions were just what wa wanted. All manufacturers would supply distribution curves of candle power for their lamps, if certain that these would be put to proper use From his experience abroad he disagreed with the remark that Natur provided a green surface where needed.

Mr. V. H. MACKINNEY referred to the use of a white card with th Holophane Lumeter for ascertaining illumination, and described a num ber of tests he had made with a model room and wall papers of variou colours to ascertain the amount of energy necessary to give the sam amount of illumination in each case, and also with different distribu tions of the light.

Mr. T. E. RITCHIE did not know of any really shadowless illumination

Mr. J. G. CLARK asked whether in a room of given size the illumina tion varied inversely as the square of the linear dimensions.

Mr. W. R. RAWLINGS thought the authors had overlooked the questio of comfort, as their remarks seemed to advocate the use of white wall Again, rooms were generally not square, and pictures and curtains ha to be taken into consideration. Moreover, it was impossible to lay dow fixed rules : each room had to be considered by itself.

Mr. J. HEWITT referred to the necessary points to be considered, vi the avoidance of glare, the sudden changes from bright to dark surface and eye strain.

Mr. HAYDN HARRISON, in reply to Mr. Eck, said that the latter shou not go to countries for the conditions in which his eyes were not adapte

Mr. WALDRAM, in reply, remarked that tests on small models were n easy. His experiments showed that tests on a room 10 ft. square we not comparable with results in larger rooms. He thought that t illumination more nearly varied inversely as the linear dimensions th as the square of these. His experience was that the Holophane Compa were the only firm from whom he could obtain the desired information

After the CHAIRMAN, Mr. R. J. Wallis-Jones, had made a few remar the discussion was concluded.

AN ELECTRO-DYNAMIC METHOD OF INVESTIGATI THE INTERIOR OF THE EARTH.

BY DR. H. LÖWY.

Summary.—A brief description is given of a method of investigat the interior of the earth due to experimental researches by the Aut and Dr. G. Leimbach. This is based on the use of electric wa whose course will depend upon the character of the rocks in the st traversed. That such a method has not been used previously is p ably due to the idea that the earth is too good a conductor to measurable results.

Until recently, geological methods were the only means av able for obtaining an exhaustive or detailed knowledge of interior of the earth. The employment of these methods, has generally meant the extrapolation of known facts to the known. To seismology we are indebted for the first d method. In the present article the author gives an accou another direct method which may perhaps be suitable for tending the results obtained seismologically in certain resp While, for instance, seismology enables conclusions regar the elastic properties of the earth to be obtained, the

Digitized by Google

methods allow the interior of the earth to be explored with regard to its electrical properties. These methods depend principally upon the fact that electric waves—as theory also shows—pass through dry earth and rock without any considerable damping. Researches on this question which have been undertaken on a large scale by the author and Dr. Gotthelf Leimbach are described below.

It is clear that when electric waves pass into the earth to a considerable distance, any buried metal surfaces which are there present must be discovered by these means. In practice, two arrangements are employed, which may be termed the reflection and absorption methods respectively.

In the first method a certain point, A, of the earth's surface is connected to a slanting antenna, AB. If the waves which this antenna transmits meet a medium, M, whose electrical conductivity or dielectric constant is very different from the corresponding constants of the surroundings, they are reflected. Then they pass to a determined point on the earth's surface, which is connected to the receiving apparatus A′B′. Both receiver and sender operate as a directive system, thus allowing the waves which are transmitted directly through the air or the earth to be separated from those which are reflected. When

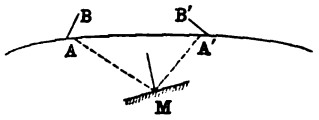

FIG. 1.

the angle of the receiver, the position of the sender being kept constant, is altered there are two maxima at the receiving end, due principally due to the direct and the other to the reflected waves.

In the absorption method bore holes some 500 ft. deep, in which the antenna is sunk, are used. If electric waves which are transmitted from the sender S (Fig. 2) are received at E_1, but not at E_2, it follows that in the path from S to E_2 lie conducting masses that, partly by absorption and partly by reflection, stop the progress of the waves.

The absorption method, in contradistinction to the reflection method, is designed for a systematic investigation of large areas. A considerable depth of bore hole is necessary, firstly, in order to be able to employ an antenna about 350 ft. long, and, secondly, in order to have the mid-surface of the antenna as far as possible in dry ground. Assuming a maximum range of 50 miles, which is certainly not too high, the area covered will be a square with a side 50 km. (31¼ miles) long. In these corners are placed the bore holes. In this way

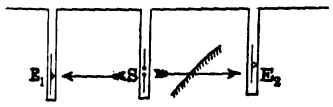

FIG. 2.

the different points at variable depths are investigated [illegible] sq. km. (1,562·5 sq. miles). For a systematic investigation of the whole lowland of Hungary 48 bore holes would be required, and were these 500 ft. deep the cost would not exceed £1,000. A great advantage of this method is, that with bore holes of known depth, it is possible to investigate points lying [illegible] deeply within the earth. On account of the curvature of the earth, for instance, waves passing between points 100 km. apart would penetrate to a depth of 3,300 ft.

Why has it come about then that so simple a means has not been used sooner? There may be two reasons for this. Firstly, everyone is accustomed, from their earliest lessons [illegible] onward, to regard the earth as a conductor,* and [illegible] over-estimate the absorption of the electric waves in the earth's crust. On the other hand, the great geological [illegible] of the earth's interior has prevented many [illegible] any clear results from relations so complicated.

* The term "to earth" shows this clearly.

In a previous discussion* of this point the author has shown that neither of these views can survive an accurate investigation. At great depths (350 ft.) the dryness of the earth is in general so great that scarcely any appreciable absorption of the waves is noticeable. The conductivity of some dry layers is less than the normal conductivity of the atmosphere. The idea of telegraphing wirelessly through the earth to great distances by means of antennæ which are sunk in bore holes has, therefore, a practical value. While the mid-surface of the antenna lies in the lower limiting surface of the ground water basin, this water itself has the advantage of giving the waves a good sending surface which is only obtained, as in ordinary wireless telegraphy, between coast stations. As regards the reflection method, in which the waves pass over the earth's surface, it can only be used in very dry places, for instance, in deserts. Lastly, it was shown that owing to the heterogeneousness of the strata, reflection does not occur as at metallic surfaces. Such illusions, which would be due wholly to geological and petrographical inhomogeneities in the earth's interior, are wholly impossible.

These results were fully confirmed by the tests undertaken by the author in conjunction with Dr. Gotthelf Leimbach at the alkali works at Vienenburg, Ronnenburg and Weetzen, as well as by the author alone at the Scharleyer Erzgruben (East Silesia). The propagation of electric waves through the earth is fully established by these researches. That the absorption, in accordance with theory, is very small is shown by the similarity of the results at the receiving end obtained with identical arrangements both over and under the earth. The tests between the alkali works at Ronnenburg and Weetzen, a distance of about 1¼ miles, with the sender and receiver about 1,500 ft. underground, in which the waves were propagated through salt and anhydrite strata, have fully confirmed the author's premises. Inhomogeneities of a petrographical nature cause no reflection of the waves. The author's tests in the Scharleyer lead mines have finally shown that a small ore content of 12 per cent. makes the earth quite impassable to the waves. In all the tests symmetrical antennæ were used which were stretched out horizontally. In the first series of tests the simple Marconi apparatus was used, while afterwards the singing spark system was employed.†

From these tests it appears that the author's method has established its utility for practical working. More extended geophysical applications, which were originally in the author's mind when he undertook the researches, are dealt with in the article to which reference has already been made.

THE CONSTRUCTION OF STANDARD CELLS AND A CONSTANT TEMPERATURE BATH.‡

BY G. A. HULETT.

Summary.—The author discusses the preparation of the materials used in standard cells and the construction of the cells; he also describes a thermostat for maintaining the temperature constant to 0·01 deg.

The one drawback of the Clark and Weston standard cells seems to be the mercury salt. It is a characteristic of mercury salts to hydrolyse, that is, to interact with water and form a basic salt and acid, and mercurous sulphate is not an exception to this rule. Sulphuric acid and sulphate solutions prevent or decrease this hydrolysis, and the hydrolysis of mercurous sulphate in a zinc sulphate solution has not been detected, but it is surely present in a cadmium sulphate solution. Such a reaction need not detract from the value of the cell, for equilibrium is established as soon as the basic salt and a definite acid concentration are present, and then the potential is again a function of the temperature only. In the Clark cell the reaction has not been detected, but in the Weston standard cell the hydrolysis takes place, although it is a very slow change which does not come to equilibrium. However, this change is generally small as well as slow, and the cell has other qualities which make it valuable.

* "Physikalische Zeitschrift," XI., 1910, p. 699.

† An account of the Veinenburg tests has appeared in the "Physikalische Zeitschrift" already quoted, while the other will be dealt with in a forthcoming issue of the same journal.

‡ Abstract of an article in the "Physical Review."

Digitized by Google

As to the reproducibility of the cells, pure redistilled mercury may be obtained from reliable dealers and answers every purpose. In lieu of this, ordinary mercury is chemically purified and then distilled.

Mercurous Sulphate.—The depolariser is chiefly responsible for variations in the reproducibility and constancy of standard cells. The first explanation of the changes which caused the trouble was offered by Carhart and Hulett; evidence was given to show that the irregularities in the standard cells were due to the presence of a basic mercurous sulphate which had been formed in preparing the mercurous sulphate or in making the paste. It was also shown that mercurous sulphate is stable in a sulphuric acid solution when the concentration of the acid is molecular (98 grammes H_2SO_4 to a litre) or greater, but when the acid strength drops below this value the mercurous sulphate begins to hydrolyse with the formation of a basic salt, soluble with difficulty—$Hg_2(OH)_2 . Hg_2SO_2$. It was therefore found possible to suggest conditions for preparing the mercurous sulphate and making the paste so as to exclude the basic salt. The cells made under these conditions did not require the usual ageing, but showed a constant value at once, and were in exceptionally good agreement.*

It is easy to prepare mercurous sulphate chemically and with sufficient sulphuric acid present to prevent hydrolysis, but there is the inclusion and isomorphism of nitric acid, nitrates or other substances to be considered, and while the depolariser made by these chemical methods does, with the proper precautions, give correct values to the standard cells, it is our experience that the electrolytic mercurous sulphate gives on the whole the most uniform and reproducible values.

The electrolytic method has the distinct advantage that only mercury and moderately dilute sulphuric acid are used and the only

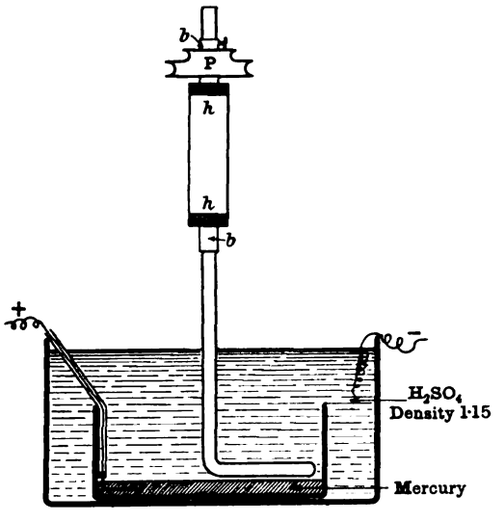

Fig. 1.

oreign substance to be looked after is sulphuric acid, which may be effectively removed as indicated below. We used an acid having a density of 1·15, made by pouring one volume of concentrated sulphuric acid into six volumes of water. When this acid is electrolysed between a mercury anode and a platinum cathode, mercurous sulphate is formed and goes into solution at the anode, but when the acid is saturated (0·2 gm. Hg_2SO_4 to the litre) the solid mercurous sulphate appears and covers the anode. At the cathode, hydrogen is liberated and a little mercury forming about 9 gm. of the salt per ampere-hour. If the mercurous sulphate is allowed to collect on the anode to any great extent, a secondary reaction may take place, but this is to be avoided, and a stirrer has been employed to keep the mercurous sulphate in suspension in the electrolyte while the current was passing, but only a limited amount of mercurous sulphate could be formed at a time.

Lately we have improved the method by using an inner dish to hold the mercury and so arranged that the mercurous sulphate passed over the rim of the inner dish and collected in the space between it and the outer dish. Fig. 1 shows the arrangement.

A motor driven stirrer was used and was made from a glass rod which was bent at a right angle and so arranged that the L part of the stirrer passed over and near to the surface of the mercury. This stirrer was held in a brass tube, *bb*, which also carried the pulley, *p*. This brass tube turned in bronze bearings in the tube, *hh*, which was firmly held by clamps (not shown). It was found to be important to have the stirrer well made so that it worked smoothly and with certainty.

* "Trans." Amer. Electrochem. Soc., 5, 71.

After the stirrer was running uniformly at the rate of some 200 revs. per min., the current was turned on. With fresh acid a skin formed on the surface of the mercury, but by breaking-and-making the current several times until the acid became saturated with the mercurous sulphate, and the solid sulphate appeared throughout the acid then there was no further trouble. The position of the stirrer was such that it did not unduly agitate the mercury. The mercury sulphate formed was carried up by rotating liquid and settled in the space between the two dishes, and much more readily when the rotation of the inner dish was retarded. This was easily accomplished by inserting glass plates edgeways down into the acid and allowing them to rest on the edge of the inner dish. With a current of from 1 to 2 amperes per 100 square cm. of mercury anode surface the product obtained was gray, due to finely divided mercury. The presence of this finely divided mercury is an advantage in checking any tendency to oxidation. Generally, 50 or 60 gm. were prepared at a run, and after the stirrer had been removed and the mercurous sulphate had settled most of the acid was removed, the contents of the inner dish were poured into the outer dish and all well stirred for some time; then the acid, with the suspended sulphate, was poured into a clean dish, and after the sulphate had settled the acid was returned to the mercury, stirred, and again decanted, and this was repeated until the mercury and mercurous sulphate were separated. The product was transferred to a glass stoppered bottle, covered with a little of the acid and kept in a dark place until needed.

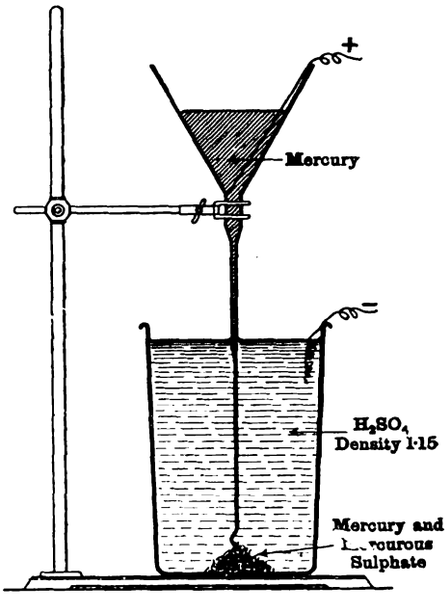

Fig. 2.

Our experience is that this gray electrolytic mercurous sulphate, prepared as just described, is the most reliable reproducible depolariser for standard cells, and that the grains are sufficiently large to avoid all effects of surface tension.

Flowing Anode Method.—Lately we have also used an interesting and very simple method for preparing electrolytic mercurous sulphate. A fine stream of mercury flowing from a funnel into the sulphuric acid is made the anode and no stirring is required. Fig. 2 illustrates the apparatus. An ordinary funnel was used, the stem was warmed in a flame and drawn down to a capillary, which was about 10 cm. in length and of such a diameter that 10 cubic cm. of mercury were delivered in about five minutes. An ordinary litre beaker glass was filled nearly full with the sulphuric acid (density 1·15) and the funnel adjusted so that the tip of the capillary was just under the surface of the acid. A short platinum spiral was hung in the acid and served as cathode, mercury was poured into the funnel, ran through the capillary and formed a spray as it entered the acid; but when contact was made with the mercury in the funnel and a current of from 2 to 3 amperes was passed, the spray changed to a cylinder of flowing mercury which extended to the bottom of the beaker and looked like a wire. It was distinctly gray save for a short distance at the top, which was bright mercury.

M. Coste and M. Etaix have used an alternating current in preparing mercurous sulphate. The flowing electrode method also permits us to use an alternating current and very simply. Two funnels were prepared with the same length of capillary stems and of the same diameter. These funnels dipped into the same beaker of sulphuric acid and the two streams of mercury were used as the electrodes.

Digitized by Google

A 60-cycle alternating current was used and so regulated that there was no arcing between electrode and electrolyte, and thus a current of about 5 amperes was used. The efficiency here is as great as with the direct current, about 9 grammes of mercurous sulphate per ampere-hour.

With the flowing anode method the preparation is white, even with large current densities, and the sulphate is easily separated from the mercury by decanting it with the electrolyte. Cells made with these preparations as depolarisers show a slightly higher value than with the gray electrolyte previously described. The alternating current preparation seems to be the better of the two, but they have not been tested for a sufficient length of time if we are concerned with the fifth decimal place in the E.M.F. of the cells.

The Paste.—The problem is to prepare a mixture of mercurous sulphate, zinc or cadmium sulphate and saturated solution, but to avoid the presence of sulphuric acid and basic mercurous sulphate. The only impurity in the electrolytic mercurous sulphate is the sulphuric acid in which it is made and preserved, but any attempt to remove this acid by washing with water introduces the basic salt. Formerly we used alcohol, which was subsequently removed by washing with the saturated zinc or cadmium sulphate solution, for we have found that this preliminary washing with alcohol is unnecessary and that really only three washings with the saturated sulphate solution are necessary, when certain precautions are observed. (A Gooch crucible, filtering apparatus and good suction were employed.)

A large agate mortar was used in mixing the components of the paste. Zinc or cadmium sulphate crystals, about equal in volume to the mercurous sulphate, were crushed, a few cubic centimetres of the saturated solution being first added to the crystals to prevent partial dehydration by the crushing. After the crystals had been ground to a fine powder, the mercurous sulphate was added and all thoroughly mixed with enough of the saturated solution to make a thin paste and of such a consistency that it readily flowed from a 5 mm. tube. Unless the mercurous sulphate was gray a little mercury was ground up with the crystals and mixed with the paste. In all the operations of preparing the depolariser and making the paste, direct sunlight or undue exposure to light was avoided.

Zinc Sulphate.—Zinc blend, from which this salt is obtained, generally contains cadmium and manganese and often lead and tin. The salt is isomorphous with the other vitriols—iron, magnesium, cobalt, nickel and copper, but none of these metals, in the small amount usually found present in zinc sulphate, seems to affect the E.M.F. of the Clark cells. Sulphuric acid is to be excluded. Zinc sulphate as obtained in the trade generally contains less than the theoretical amount of water of crystallisation, due to efflorescence, so it is best to recrystallise the salt, and at room temperature, in order to ensure the heptahydrate.

Zinc Amalgam.—Zinc is one of the more soluble metals. With an excess of zinc we have, for each temperature, a liquid amalgam of definite composition, and in equilibrium with a solid phase which is pure zinc.

At	0	the liquid amalgam contains	1·35	per cent.	of	zinc.
	15	„ „ „	1·74	„	„	
	20	„ „ „	1·99	„	„	
	25	„ „ „	2·18	„	„	
	39	„ „ „	2·85	„	„	

There seems to be no difference between the potentials of amalgams made from "chemically pure" zinc and mercury and amalgams made from the most highly purified metals, so the "chemically pure" materials serve every purpose. Zinc dissolves but slowly in mercury and the amalgam oxidises readily when hot, but we have had no trouble with this amalgam since using the following method: A 2 cm. hole was cut in a piece of asbestos cardboard and an ordinary porcelain crucible was pushed into this hole so that it was about half way through, the board was placed on a tripod and the crucible was charged with 7 gm. of chemically pure zinc, and then 50 gms. the weight of mercury was added. A small adjustable Bunsen flame was placed under the crucible and the contents heated, without stirring, until the zinc had all dissolved. This takes a temperature near to the boiling point of mercury, and the crucible is covered with a little watch glass. The flame was now pushed 2 or 3 centimetres to one side, and when the crucible cooled down to 150 deg. the amalgam was readily transferred to the cells with a pipette.

Cadmium Sulphate.—$CdSO_4.8\,3H_2O$ is a very soluble salt, but is peculiar in that the *rate* of solution is exceptionally slow, so that considerable attention is needed to prepare a saturated solution. The solubility changes only slightly with the temperature and the hydrate is stable up to 74 deg., where it changes to the monohydrate. Cadmium sulphate does not seem to be isomorphous with the zinc salt, and consequently is obtained in a sufficiently pure state in the trade, but one may obtain such beautiful crystals that it is worth while to recrystallise the salt. Attention is to be given to the preparation of a saturated solution of cadmium sulphate on account of the slow rate of solution of these crystals; 100 cubic cm. of the saturated solution requires 75 cubic cm. of water and 86 gm. of the crystals, but a considerable excess of the crystals is to be used and stirred over night with a motor-driven stirrer.

Cadmium Amalgam.—Cadmium is the most soluble metal in mercury; the saturated amalgam contains the following percentages of cadmium:—

At	Per cent. cadmium.
0°	2·5
15°	4·4
25°	5·6
35°	7·1

With an excess of cadmium the solid phase is not cadmium but an isomorphous mixture of cadmium and mercury. In view of the great solubility of cadmium at ordinary temperatures it does not seem well to use less than 8 per cent of cadmium in the amalgam. The question of equilibrium in this amalgam needs further investigation; it is a much more complicated system than is the zinc amalgam. We have used for some time a 10 per cent. amalgam for our cells and make it quite accurately and uniformly as follows: 99 gm. of mercury were placed in a little crystallising dish, 5 cm. or 6 cm. in diameter, and 25 gm. of the clear cadmium sulphate crystals (43·82 per cent. Cd) were placed on this mercury and then about 50 cubic cm. of distilled water was carefully added and made acid with a drop of sulphuric acid. A flat platinum spiral was so adjusted that the spiral was just beneath the surface of the water and contact was made with the mercury which was cathode. When 2 or 3 amperes were used the cadmium was deposited in the mercury about as fast as the sulphate dissolved; then when the crystals had all disappeared the current was increased to 4 or 5 amperes for half an hour. This insured a complete deposition of the cadmium and also liberated enough heat to melt the amalgam. The acid was finally removed by a *pipette* or syphon and at the same time distilled water was run in. This washing continued until the current dropped to zero.

We have prepared cadmium sulphate and cadmium of the highest degree of purity, also zinc sulphate and zinc, and constructed cells with these materials, but the E.M.F. of these cells did not differ from that of the cells made with materials prepared as described above. This result is what we would expect when we consider the factors controlling the potentials at the anodes and cathodes of these standard cells.

The Glass Parts.—The "H" cell proposed by Lord Rayleigh has proved to be the most practical form of cell. It is easily filled and allows the contents of each electrode rapidly to take up the temperature of the bath. The 0·2 mm. platinum wire leads are sealed through the glass so that all but the tip end is covered with a sheath of glass. The wire is first sealed in so that the end is only just through the glass and then, while the glass is still soft, the wire is pushed in about 5 mm. and covers itself with a sheath of glass leaving only the tip exposed. Wires sealed in this way give uniform contact with the mercury or amalgams and are less liable to cause subsequent cracking of the glass, especially when a fine wire is used.

The mercury, amalgam and paste are each from 10 mm. to 15 mm. in depth. A few crystals are placed on top of the paste and on the amalgam a layer of crystals not over 10 mm. in depth. Only a small amount of the crystals are necessary for either the Clark or Weston cell, while a large excess may grow together and cause trouble. The cell is filled to the top of the cross tube with the saturated solution and then the glass parts are sealed off 2 cm. or 3 cm. above the liquid by using two small blast flames which impinge on opposite sides of the point to be sealed.

The difficulties we have encountered with these cells are the tendency of the glass parts to crack (which is most pronounced in the amalgam leg of the Clark cells), and the fact that the contents of the cell are not accessible. This difficulty was recognised by Lord Rayleigh in recommending the cork seal. The trouble with this has been that the cork was generally in contact with the liquid and so leaked sooner or later. We have used for some time a form of cell which avoids these difficulties; the glass part is the simplest possible (Fig. 3). Thin-walled tubes, 20 cm. long and 12 mm. in diameter, are closed at one end and blown out at the side about 5 cm. above the closed end. Two of these tubes are joined directly together giving the advantages of the test-tube form. No platinum wires are fused into this part of the cell. These cells are closed by corks which are 15 cm. above the liquid of the cell and are never wet and do not need to be covered with wax. These corks carry the long narrow tubes which enclose the contact wires, and these may be removed and replaced at any time. This long form of cell is found

Digitized by Google

to have many advantages in handling in the bath; several may be bound together in a very compact form and the contents of these cells most readily take on the bath temperature while the insulation is perfect in any kind of a bath liquid.

The details of the contact wire and protecting tubes are also shown in Fig. 3. A piece of tubing 3 mm. in diameter is softened in the flame and drawn down so that the part which is to pass through the contents of the cell is not over 2 mm. in diameter. This narrow part is about 6 cm. long, while the total length is about 22 cm. A piece of 0·1 mm. platinum wire about 10 cm. long is soldered to a 20 cm. piece of silk covered copper wire (No. 32). This wire is passed into the protecting tube until the platinum wire projects one or two millimetres from the narrow end of the tube and this thin end is sealed in the flame. A bit of wax is run into the upper end to hold the wire securely. Six cells are made at one time and all bound together and then the negative or anode wires are twisted together and the exposed ends soldered so that only one contact need be made for the anodes of all six cells. The positive or cathode wires are scraped to remove the covering, and then each one is wound about a small piece of millimetre copper wire which is forced into the warmed wax in the top of the tube leaving about a centimetre exposed, and here a good contact is easily and rapidly made with a pinch connector. It is well to amalgamate the platinum tip of the contact wire just before it is inserted into the contents of the cell. This is readily done by holding it for a few minutes in boiling mercury (in a test-tube).

E.M.F. of Standard Cells.—We have made both Clark and Weston cells at intervals since 1903 and according to the preceding specifications. A dozen Weston cells, made at one time, often agree among themselves to 1 part in 100,000, but in time the agreement is not so good; in a year or so the variations may be noticeable, and when compared with a freshly made set of these cells it has been found

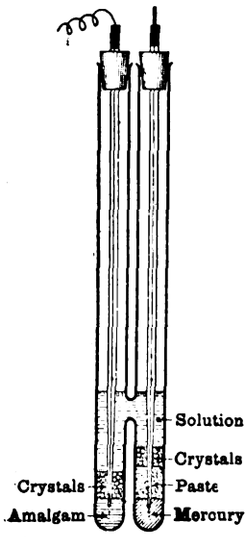

FIG. 3.

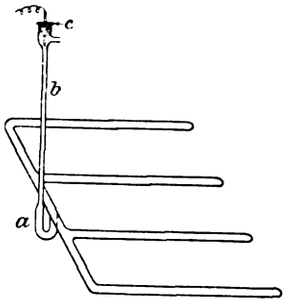

FIG. 4.

that all the older cells have decreased and some of them very noticeably. Clark cells have also been made at intervals during the last seven years and the agreement among themselves of any "set" of these cells is about the same as that of the Westons, but the Clark cells made at different times are in better agreement and none of them have shown an E.M.F. decreasing with time, such as is noticed in some of the Weston cells. It seems necessary, therefore, to make the Weston cells at intervals of about six months and reject those which fall to low values. We make both Clark and Weston cells at such intervals, and the cells are kept all in a constant temperature bath which does not vary over 0·01 deg. from 25 deg. Taken all together these two kinds of cells with the aid of a thermostat give us a standard which is independent of time and is reliable and reproducible to one or two parts in 100.000. The value in absolute units of this standard of E.M.F. is, of course, not known to anything like this degree of accuracy, but whenever the absolute value is more accurately determined, all work which has been based on this constant may be recalculated if necessary, so we are justified in giving the assumed value to the fifth decimal place. Assuming that the Clark cell gives 1·4330 volts at 15 deg. and using the customary temperature formula the Weston standard cells are found to have the value 1·01840.

The Thermostat.—The Weston cell has only about one thirtieth of the temperature coefficient of the Clark cell. This was a decided advantage before thermostats were used, but for electrical measurements which make any pretence to accuracy an automatically controlled bath is indispensable for both types of cell, so the temperature coefficient is of no consequence. It is our experience that it takes a considerable time at a given temperature for *all* the cells of a set of standards to attain their true value. We generally allow a week. It is, therefore, necessary to have an automatically controlled bath, and 25 deg. has been chosen. Our thermostat is an electrically heated and controlled kerosene bath which keeps well within 0·01 deg. for any length of time It consists of a tank made from galvanised sheet iron, 50 cm. by 65 cm. and 50 cm. deep, which rests in a box on legs. The space between the box and the tank (6 cm.) is packed with excelsior, and the top of the tank projects about 2 cm. above the top edge of the box. A cover, 100 cm. by 100 cm., was provided, and the centre (50 cm. by 65 cm.) cut out so that the top of the tank fits into this place and is flush with the top of the table part when assembled. Plate glass strips of convenient widths cover the tank proper. About 100 litres of kerosine serve as the bath liquid, and are found to be very clean and easily kept dry by a dish of calcium chloride suspended in the upper part of the tank. A motor-driven stirrer was neessary.

The regulator and heater have received most attention, the aim having been to get large surfaces well distributed in the bath liquid. Both the regulator and heater are supported by a frame about 10 cm. above the bottom of the tank. This frame was made of brass tubing, 40 cm. by 55 cm., with two cross pieces and is supported by four legs. Fastened to the under side of this frame is the glass part of the regulator (Fig. 4), which contains the toluene and mercury, and the expansion or contraction of these liquids makes or breaks a contact of the relay circuit and so controls the heating current.

Sparking between the mercury and the platinum point causes the mercury to become "dirty," changes the meniscus and thus causes a slow drift of the bath temperature. It is customary to put a condenser in parallel with this contact, but we have had much better results by arranging to use a small current of low voltage in the relay circuit. We find that our mercury contact surface remains perfect for months at a time and makes-and-breaks contact with the platinum point at exactly the same temperature.

With the arrangements we have, the heating current is made or broken by a change in the bath liquid of only one or two thousandths of a degree. For constancy, and to avoid oscillations of the bath temperature about the desired point, it was necessary to have the bath well insulated. This was accomplished with the 6 cm. of excelsior packing between the tank and containing box and the plate glass cover. Also, it was especially important to have a small amount of heat liberated in the unit of time, and well distributed in the bath liquid. Our heating coils consist of 0·25 mm. nickel wire wound on 10 mm. glass tubes shellacked to hold the wire in place. The resistance of our coil is about 120 ohms and is connected with the 110-volt alternating-current lighting circuit, but we also use an external resistance, as 0·4 ampere is sufficient to control the bath, even with very considerable variations of the room temperature.

THE "THOMAS" ELECTROMECHANICAL TRANSMISSION FOR MOTOR VEHICLES.

An interesting test of a commercial motor vehicle by the Royal Automobile Club has been taking place during the past 10 days over an exceptionally hilly route in Kent. The motor vehicle in question is a 30-40 H.P. lorry fitted with the "Thomas" electromechanical transmission, and the first section of the trial comprises a 2,000 mile constant running (day and night) test under full load between Bromley Common and Cooper's Green (one mile from Uckfield). The route, which is about 37½ miles long, passes through Sevenoaks and Tunbridge Wells. This route is traversed continuously (except for short intervals during change of observers, drivers, &c.), and the double journey of 75 miles is completed three times every 24 hours. As mentioned above, the route is of an exceptionally hilly nature, there being practically no level stretches of road, whilst the gradients are very steep. This road was chosen by the Company so as to provide a severe test of their gear, and the test is the more exacting in that the Automobile Club stipulated a 12-mile per hour speed limit.

The lorry, of which a view is given in Fig. 1 herewith, carries a net load of about 3½ tons. The weight of the Leyland chassis is 3 tons 19 cwt., and the total weight of the loaded vehicle under test is about 7 tons 18 cwt.

The "Thomas" electromechanical transmission system differs from other systems devised to give a wide speed variation by means of electrical machines, in so far that there are two distinct paths of power between the engine and the load shaft—one mechanical and

Digitized by Google

the other electrical. This arrangement is obtained by means of planetary gear in conjunction with two small electrical machines. These units are so arranged that the greater proportion of the engine power is transmitted direct mechanically.

Fig. 2 shows the arrangement. The casing D forms the flywheel of the engine and is direct coupled to it. Inside this casing are two planet pinions P and P_1 of different diameters keyed to the same spindle; this spindle is supported in the sides of the casing and is free to rotate about its own axis. The planet pinions P and P_1 mesh with the two sun pinions W and W_1, which are rigidly connected to the independent shafts H and K. On the shaft K is mounted the armature B of an electrical machine, and on the shaft H (which is the load shaft) is mounted the second electrical machine C. These two machines, B B_1 and C C_1, have their field windings in series with their armatures, and are connected in series by the operation of the controller.

FIG. 1.—VIEW OF LORRY UNDER TEST WITH "THOMAS" TRANSMISSION.

There are thus two paths of power between the engine and the road wheels—the first, a direct mechanical path from W along the shaft H; and the second, an electrical path from W_1 through two electrical machines to the shaft H. If W is larger than W_1, then for a certain rotation of the casing W_1 will tend to rotate backwards and W forwards, at speeds depending upon their relative resistances to motion. It will be seen that if the speed of the casing D is constant, the speed of H will vary with the speed of K; and since the speed of K depends on its resistance to motion (and, therefore, on the load on the machine B B_1), the speed of H can be varied by changing the amount of power transmitted electrically.

The actual series of operations is as follows: The casing D is rotated by the engine at a constant speed. There being no electrical connection between B and C before starting, W_1 will rotate freely backwards and W remain stationary. To start the vehicle the circuit between B and C is closed; the current transmitted to C then exerts a large starting torque on H, and the load thereby impressed on B by this current decreases the speed of K, and, therefore, causes W to rotate. In this manner a large starting torque is exerted on the road wheels.

As B is gradually decreased in speed the vehicle accelerates until the armature K practically comes to rest. Up to this point B has been acting as a dynamo and C as a motor. If now K is forced to rotate in the same direction as the engine, it is evident that H can still further be increased in speed. This operation is performed by transmitting power from C to B—both machines now changing their functions. K increases in speed more rapidly than H, due to the gear ratio, until finally they are both travelling at the same speed. The coupling Q is then engaged, with the result that the current in the electric circuit falls to zero. All electrical losses are thereby eliminated, and a direct drive is obtained from the engine to the road wheels for the top speed.

In the lorry under test there are 10 forward positions of the controller, exclusive of the direct mechanical drive at top speed. In addition there are two reverse positions.

A 12-volt battery of 180 ampere-hour capacity, forms part of the equipment. This battery is used for starting the engine by running machine B as a motor. The current taken from the battery rises momentarily to a maximum of 100 amperes. The variation of the power transmitted electrically between the machines B and C is obtained by varying the field strengths of the two machines. For this purpose a resistance is connected in parallel with their field magnets, and is adjusted to obtain the various speeds. The resistances are contained in the controller, and as they are submerged in oil, efficient cooling is provided. It should be understood that the successful working of the system is not dependent on the battery, this being used solely for lighting and for starting the engine.

For running backwards electrical transmission alone is employed. The clutch Q is engaged and S disengaged; the armature B is thereby driven direct by the engine, and current is supplied to C, of which the field has been reversed. This machine then acts as an electric motor and drives the vehicle backwards. It is interesting to note that all the above operations are performed by the one control lever.

The feature of the "Thomas" system is that the electrical machines are not in use continuously, so that their rating is very high; in fact, their capacity is only about one-third the horse-power of the engine, instead of one-half, as might be expected. The weight of each electrical machine is from 5 cwt. to 6 cwt., whilst the controller weighs less than ½ cwt.

The efficiency at the lowest "running" speed is about 80 per cent. It rises from this position to a maximum of about 94 per cent. when machine B becomes stationary, and then decreases to about 86 per cent. on the tenth notch. At top speed (direct mechanical drive) the efficiency, of course, jumps to 100 per cent. It may be noted also that a higher average compression can be employed for the engine, since the latter can be run at a constant speed. As to petrol consumption, previous tests in Lancashire have shown a consumption equivalent to 9·7 miles per gallon with a three-ton load.

One of the advantages of the "Thomas" system is that electric lighting can be adopted with very satisfactory results. The question of charging the cells, which is frequently a source of trouble, is overcome by running machine B as a shunt generator when the control lever is in the top position.

The chief advantages claimed for the "Thomas" system of transmission may be summarised as follows: (1) The large proportion of power transmitted direct mechanically and therefore the high efficiency. (2) The small proportion of power transmitted electrically and therefore the low cost and weight of the electrical machines. (3) The large number of running "speeds"—the full engine power being thus always available. (4) No break in the transmission of power during the changing of speeds. (5) High and smooth acceleration. (6) Direct drive on top speed. (7) Freedom from noise and shock and reduction in wear and tear. (8) Self-starting of petrol engine. (9) Electric lighting.

We inspected the lorry on Monday last, and saw it ascend the steepest hill on the route. As we also saw the capabilities of the system from trial runs on a car fitted with the gear, we can testify to the smooth changing of speeds and to the simplicity of the control. We may mention that braking is obtained mechanically in the usual way.

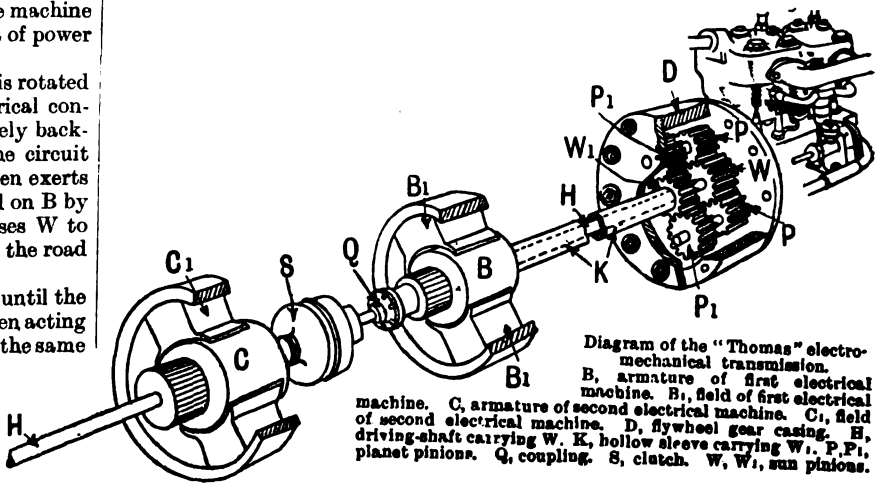

Diagram of the "Thomas" electro-mechanical transmission. B, armature of first electrical machine. B_1, field of first electrical machine. C, armature of second electrical machine. C_1, field of second electrical machine. D, flywheel gear casing. H, driving-shaft carrying W. K, hollow sleeve carrying W_1. P, P_1, planet pinions. Q, coupling. S, clutch. W, W_1, sun pinions.

FIG. 2.

In conclusion, we may say that the lorry had on Monday last completed 1,200 miles of the trial, and we understand that the gear had given absolutely no trouble whatever.

We desire to express our indebtedness to Mr. G. Thomas, the inventor of the system, and Mr. K. J. Thomson for the trouble they took in explaining all the features of the gear and in demonstrating its capabilities. We have no doubt that it will come through the present arduous test with credit, and we shall await with interest the motor omnibus fitted with this gear which is shortly to be placed in service on the London streets.

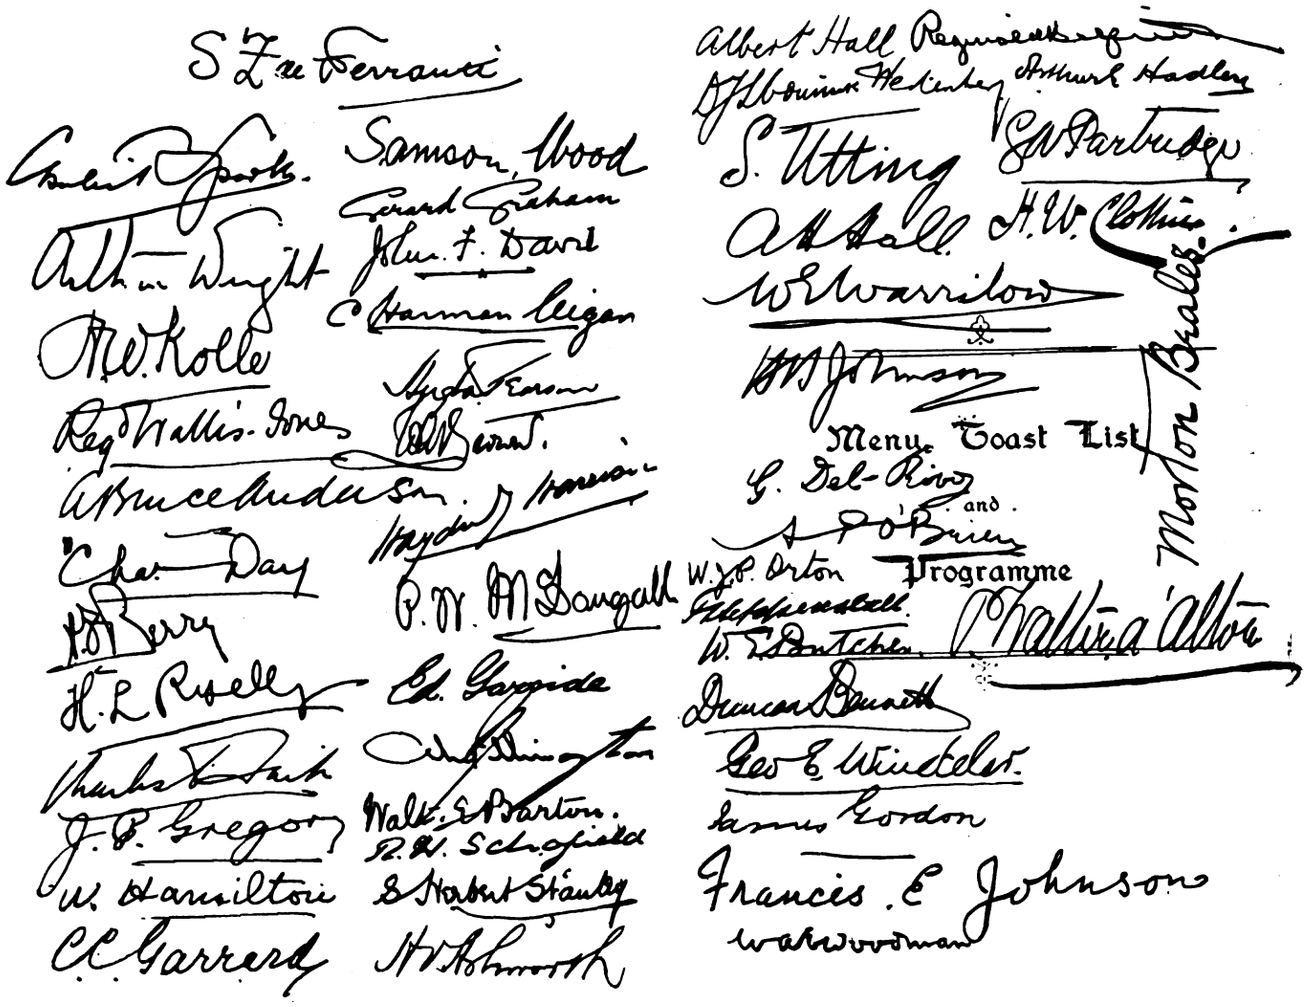
OLD FERRANTIANS DINNER.

It was a unique gathering of electrical men which assembled on Saturday last at the Trocadero to do honour to Mr. S. Z. de Ferranti. Those old Ferrantians who were able to be present comprised electrical engineers who had been associated with Mr. Ferranti in the early days of the Deptford undertaking, at his works in Charterhouse-square, London, and afterwards at Hollinwood, Lancs. The function was occasioned by the fact that Mr. Ferranti is this year President of the Institution of Electrical Engineers, an honour which had been somewhat tardily conferred upon him considering his long and prominent association with the industry. Mr. Ferranti's election as President for the second year in succession was happily coincidental with the date fixed for the dinner. The chair was taken by Mr. C. P. Sparks, and about 60 old Ferrantians were present. Upwards of 120 men were apprised of the function, but many were prevented from attending owing to business or other engagements. Among these were Mr. C. H. Wordingham, Mr. W. Cramp, Mr. C. Vesey Brown, Mr. W. L. Madgen, Mr. H. C. Sparks, Mr. W. S. Toplis, Mr. D. Martin, Mr. J. K. Stothert and Mr. A. Hobbs, who expressed their regrets at being unable to attend.



Old Ferrantians Dinner; Signatures on Mr. Ferranti's Menu Card.

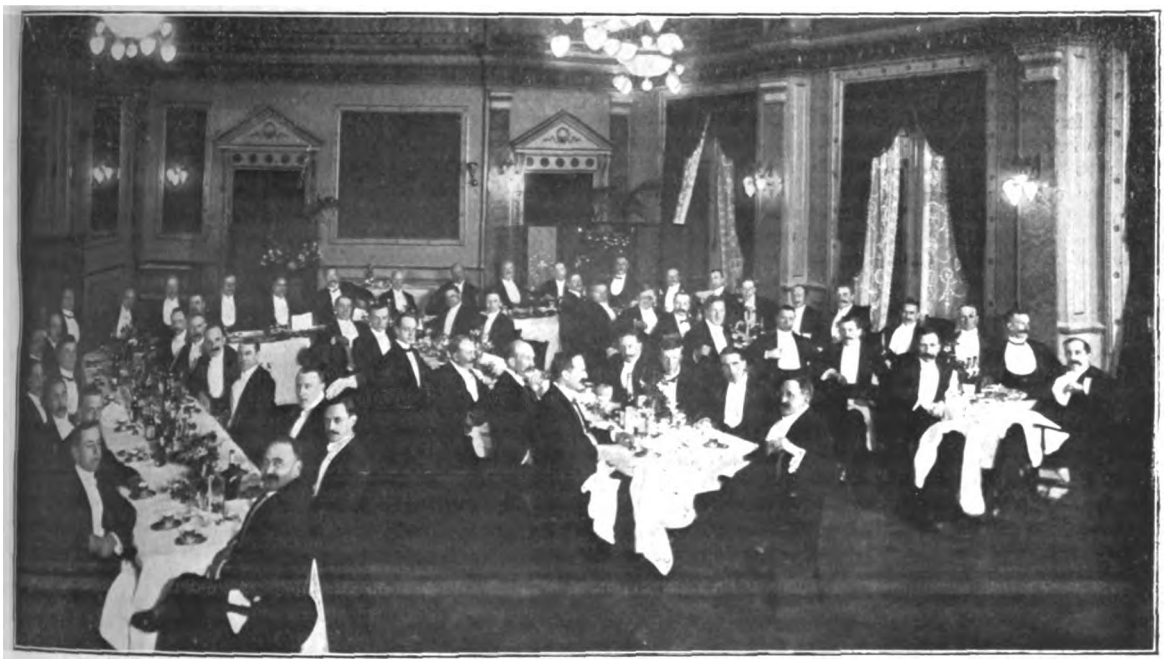
The Chairman was supported by Mr. G. W. Partridge, Mr. H. W. Kolle, Col. P. W. D'Alton, Mr. A. B. Anderson, Mr. A. E. Hadley, Mr. Arthur Wright, Mr. R. Belfield, Mr. Chas. Day, Mr. M. B. Field, Mr. A. Jacob, Mr. H. W. Clothier, Mr. Haydn T. Harrison and Mr. G. Del Rivo. We reproduce Mr. Ferranti's menu card on which most of the old Ferrantians present signed their names.

Mr. C. P. Sparks, in proposing the toast of the evening, that of Mr. Ferranti, expressed the regret of Lord Crawford at being unable to take the chair. He was pleased to see so many members of the old Ferranti staff present, and was gratified to notice that practically every period of Mr. Ferranti's work was represented, from the "Old Guard" in the Deptford days to the heads at Hollinwood at the present time. He referred to the magnetic influence of Mr. Ferranti and the beneficial effect which it had had upon all the electrical men who had been associated with him, and particularly those engaged on his staff. For the past 25 years Mr. Ferranti had maintained an extraordinary enthusiasm. He had been able to look ahead, and see possibilities which had subsequently become eventualities. His work in connection with the Deptford scheme was well known, but as a permanent reminder of it, and also a memento of the evening's gathering, each guest had been presented with a small piece of the original 10,000-volt concentric main which was laid from Deptford to the Grosvenor Gallery and had been in use for 21 years. These pieces of cable had been made up by Mr. G. W. Partridge, chief engineer of the London Electric Supply Corpn., and presented by him as menu holders. That cable was an indication of Mr. Ferranti's early insistence upon simplicity in the design of everything electrical with which he was associated. Mr. Sparks then reminded his audience of the work which Mr. Ferranti had been doing as President of the Institution of Electrical Engineers during the past year. His efforts to consolidate electrical interests and his earnest wish that the Institution itself might prove more helpful to its members and to the industry generally were much appreciated. He regarded it as auspicious that the occasion coincided with the election of Mr. Ferranti as President for the second year in succession, and he felt sure that during his next term of office Mr. Ferranti would be able to carry towards practical realisation the good work he had begun. In proposing the toast Mr. Sparks presented Mr. Ferranti with a solid silver inkstand, which had been subscribed for by old Ferrantians in all parts of the country. The toast was drunk with great enthusiasm.

Mr. Ferranti, in rising to respond, was visibly moved by the ovation. He expressed his sincere thanks for the present, and said that he should value it on account of the good feeling which existed between his staff and himself. He should also prize it in remembrance of his long association with his staff from the early days of the industry to the present time. He looked upon the gathering as unique in the annals of the electrical industry. He could see men around him who had assisted at the initiation of public electricity supply in the early eighties. He also felt that the assembly typified the extraordinary progress which had been made since his first intro-

Digitized by Google

duction to the industry. He recalled his own early efforts when Grove and Daniell cells were the only known sources of practical electricity. He caused considerable amusement by referring to his boyish ambitions to insulate magnetism, and how he could not realise at the time what a tremendous revolution might be effected if such a thing were possible. He had always endeavoured to be enthusiastic, and he was not sure if his enthusiasm had been communicated to his staff, or whether he had not derived a considerable amount of it from the staff themselves. It required great faith in the Deptford days. As a practical instance of it he related how Mr. H. W. Kolle risked his life by holding a cold chisel which was driven through the first concentric main while this was alive at a tension of 10,000 volts. Mr. Ferranti reminded members of his old staff of the paucity of materials in the early days, when mica, though certainly known, was practically unworkable, and only ebonite was a reliable insulator. The pieces of cable which each man had before him on the table were practical examples of the first use of a cheap insulator, paper and the refuse of candles being employed to insulate one conductor from the other. He was glad to see round him the faces of such men as Mr. R. Belfield, Col. P. W. D'Alton, Mr. Samson Wood and Mr. W. Lawrie. In Col. D'Alton he recalled a man who was



THE OLD FERRANTIANS AT DINNER.

[illegible] to take charge at Deptford mainly on the recommendation [illegible] he had gone under the sea in a submarine boat. In those [illegible] times the man who could do such a thing was especially suited [illegible] after the Deptford station. Mr. Samson Wood was the [illegible] man to build up the zigzag armature for his early copper-type [illegible]. The armature of this machine, which he noticed was [illegible] on the front of the menu card, was not wound with a [illegible] conductor, but four separate conductors in parallel. It was the [illegible] instance of a machine from which an equal E.M.F. could be [illegible] with multiple conductors. He was now able to look back [illegible] satisfaction on the efforts of the pioneers of direct-current [illegible] to bring about the downfall of alternating-current high-[illegible] supply. The scaremongering indulged in at the time was [illegible] to impair seriously the success of the Deptford undertaking. Mr. Ferranti then expressed his pleasure at being elected to remain in [illegible] as President of the Institution for another year, and referred [illegible] to the plans he hoped to develop whereby the members might be more mutually helpful than heretofore in restricting the undue amount of competition which seriously threatened the progress of the industry. While cheap machinery and plant might be useful enough from a public point of view, at the same time, in an industry such as that of electrical engineering, large profits were required to carry on developments and research work. When these profits could be shown, then capital would be attracted to the industry, and manufacturers would get an even greater recompense for their efforts.

In conclusion, Mr. Ferranti again thanked those present for attending the dinner, and he further assured them of the immense amount of pleasure it had afforded him. He would take away the most pleasant recollections of one and all of those who in different ways and at different times had proved so helpful to him.

Mr. HAYDN T. HARRISON proposed the remaining toast, that of the chairman, Mr. C. P. Sparks, in an amusing speech, and recalled the early days at Charterhouse-square, which immediately preceded those of the "Old Guard." He remembered that Mr. Sparks had put him in the sulphur room, and that incident impressed upon him the force of Mr. Ferranti's remark that pioneer electrical engineers were hampered for lack of materials. He had painful recollections of the number of air bubbles which would get into the sulphur he had to manipulate. There was great laughter when he spoke of a Kelvin electro-static 40,000-volt voltmeter, which was a huge box with practically nothing inside it, and which had been sent to Deptford, but was ordered to be returned to the makers, because no one could get a circuit through it. The toast was received with enthusiasm, and Mr. Sparks replied in a humorous speech, in which he told an amusing story of the tightest corner he had ever been in in his life. This was an occasion on which he interviewed a Scotch town council to explain the cause of the failure of the electric light, and how his difficulties disappeared when his case was championed by a baillie who had had a long standing grudge against the convener of the electricity committee. The proceedings, which terminated at a late hour, were concluded by a vote of thanks to Mr. Warrilow, the hon. secretary.

Proposed Electrification of Chicago Termini.—According to the "Electrical Review and Western Electrician," the Committee appointed by the Chicago Chamber of Commerce to discuss this question has already begun its sittings under the chairmanship of Mr. Jesse Holdom. The scope of this Committee is indicated in the following terms which form part of the report of another Committee appointed to consider the scope of the investigation:—"Your Committee, to whom was referred for consideration and report the scope of the investigation necessary to be made in connection with the proposal for the electrification of railroad terminals, is of the opinion, and so reports, that the investigation necessary briefly may be stated to include: First, the necessity for the proposed change; second, the mechanical practicability of such change; and, third, the commercial feasibility thereof. These heads naturally subdivide into many specific subject-matters which, in the opinion of your Committee, will and should be developed by the expert in charge." It was decided that the three phases of the investigation should be taken up simultaneously, and that the progress of the work should be permitted to dictate the relationship of each to the others.

PRACTICAL ASPECTS OF PRINTING TELEGRAPHY*

BY DONALD MURRAY, M.A.

Summary.—The author first discusses the field for printing telegraphs. Their use is chiefly in connection with land lines between centres of population, and they will assist materially the co-operation between telegraph and telephone. He next gives a detailed account of the difficulties encountered in connection with the development and practical application of printing telegraphs, and finally describes the Murray automatic system and the new Murray multiplex system.

The Paper is divided into three parts, as follows: Part I., which discusses generally the field for printing telegraphy; Part II., dealing with the practical difficulties in the way of printing telegraphy; and Part III., describing some printing telegraph apparatus designed to overcome these difficulties.

Part I. (Introduction).

No doubt in time wireless printing telegraphy will receive more or less attention, but it will not be of much importance, in this generation at any rate, because there cannot be any saving of line or line maintenance when there is no line. Any saving of labour that might be effected by wireless printing telegraphy is of trifling importance, because the wireless operator has to be in attendance in any case, and the speed of signalling is low.

For railway work printing telegraphs have hardly been employed at all up to the present, and as the telephone is gradually displacing the telegraph for most railway work in America, and therefore no doubt in time in other countries also, printing telegraphy does not appear to have any extensive possibilities in conjunction with railways. In time, printing telegraphy will probably play a considerable part in connection with ocean cables, but up to the present hardly anything has been done in this direction, because the conditions to be fulfilled are extremely complicated. There cannot at present be any line saving, because ocean cables are already utilised up to their full capacity. It will be possible to effect a slight saving of time and some saving of labour, but the apparatus will necessarily be of a very delicate and intricate character. The expenditure will necessarily be heavy, and the saving will not be more than about £300 or £400 a year on each cable at each end.

So far as the present position of printing telegraphs is concerned, the Hughes tape printer carries the bulk of the telegraphic traffic on the Continent of Europe, and it has done so for nearly half a century, about 3,000 Hughes instruments being now in use. Most of the telegraph traffic between Great Britain and the Continent is also carried by the Hughes, but this machine is only employed outside of Europe to a very slight extent. During the past 30 years the Baudot system, which may be described as a multiplied Hughes tape printer, has been developed and extended in France until all the telegraph lines of any importance are equipped with it. During recent years it has also made considerable progress in Italy, Brazil, India and Russia. In Russia it is quite extensively used, most of the leading towns in European Russia being connected by it. It has likewise secured some foothold in most other European countries, Paris being linked up by it to nearly all the capitals of Europe. Great Britain has proceeded in very leisurely fashion, and, so far, has only coquetted with printing telegraphy, more or less prolonged flirtations having been carried on by the British Post Office with the Hughes and Baudot, the Buckingham, the Murray automatic, the Siemens & Halske and several other systems. The latest arrival, the Murray multiplex, may be described as the child of the British Post Office, it having been developed with the assistance of that institution. The Murray automatic system has made most progress up to the present in Germany. It has also secured a foothold in Russia, Sweden and Norway. It is in regular commercial use between Hamburg and Berlin, Berlin and Frankfurt, Hamburg and Frankfurt, Berlin and St. Petersburg, St. Petersburg and Omsk in Siberia (about 2,400 miles, with three repeating stations), Stockholm and Gothenburg, Kristiania and Bergen. A new installation with all the latest improvements is being established between London and Dublin. For various reasons, however, the use of the Murray automatic system is limited to long lines and underground cables, and there is, consequently, not a very wide field for it, especially in comparatively small countries like Great Britain. The Murray multiplex, on the other hand, is very well adapted for moderate distances, but it has not yet had time to come into extensive use. In the United States the Buckingham system was developed under the auspices of the Western Union Telegraph Co., and some 60 circuits are now equipped with the Buckingham system as improved by Barclay.

Printing telegraph inventors are still busy increasing the height of the printing telegraph scrap pile, but the substantial results over the whole wide world are summarised in the foregoing paragraphs. These results are neither extensive nor brilliant, and it is an actual fact that less than £1,000,000 sterling would cover the value of all the printing telegraph machinery on the face of the earth to-day. This is the outcome of 50 years of constant labour by scores of inventors. We have only to compare this with the gigantic extension of telephone apparatus all over the world in only a few years to realise that there must be some hampering circumstances, some peculiar difficulties and obstacles in the way of printing telegraphy.

Before considering these difficulties the author discusses the four economies of fundamental importance in the transmission of intelligence—namely, to save time, to save labour, to save line, to save office equipment—and he emphasises the heavy labour cost and loss of time in the transmission of telegraphic communications. The vital importance of printing telegraphs lies in the fact that they can greatly reduce the present waste of line and labour in telegraphy, and that they render it possible to foster the growing co-operation between the telegraph and the telephone. The telegraph and telephone are each strong where the other is weak. We can set out the points in tabular form thus:—

——	Telegraph.	Telephone.	Telegraph-telephone.
Time	Wasteful	Extremely economical	Fairly economical
Labour	Wasteful	Extremely economical	Fairly economical
Line	Very economical	Very wasteful ...	Very economical
Office equipment	Cheap	Expensive	Expensive

If we utilise the telephone as the short-line feeder and distributor for the long-line telegraph we get the ideal co-operation shown in the last column of the table. The cost of office equipment will be increased, but this will be outweighed 10 or 20-fold by the economies of line, labour and time.

If telegraph messages were charged for like telephone messages—by time instead of by the number of words—a lot of the labour cost would fall away. A merchant would then ring up the nearest telegraph office. He would be switched on to the required circuit, and he would dictate his message direct to a telegraph operator, who would type it on a rapid keyboard tape perforator. The perforated message would run through an automatic transmitter, and would be printed automatically direct from the line signals at the distant station, from which point it would be telephoned at once to the addressee. This telephone-telegram idea is already slowly emerging into everyday use. The British and other administrations now accept and deliver telegrams by telephone, and the British Post Office has actually coined the special name of "phonograms" for such telephone-telegrams. To handle "phonograms" under ideal conditions there should be a system giving either high automatic speed of transmission or at least four simultaneous transmissions in each direction on busy lines, and the speed of each transmission should be a steady average of at least 40 words a minute. Not only would quick handling and transmission of messages be necessary, but also quick reception and printing of the messages at the other end of the line ready for transmission by telephone. Printing telegraphs are a necessity for such methods of handling telegrams.

The chief stumbling-block at present is the practice of charging for telegrams according to the number of words, which involves an incredible amount of waste time and labour in counting the number of words.

In addition to the telephone as a local collector and distributor of telegrams, there appears to be a field for the small step-by-step printing telegraphs generally known as stock-tickers. The Siemens & Halske teletyper is a good example of this class of machine. These little machines, however, are more expensive and complicated and slower than telephones, and in the nature of things can only come into very limited competition with the telephone. The same remarks apply to the telewriter.

Meanwhile we have to see what steps we can take to reduce labour cost of telegrams under present conditions. The subject is very complicated and there are many obstacles, but threepenny telegrams and quick service would lead to a wonderful growth of telegraph traffic. These depend on rational co-operation between the telegraph and telephone, upon the extension of the telephone to practically every office and home, and last, but not least, upon efficient printing telegraphs. It is practically certain that in the course of the next 10 or 15 years the British Post Office alone will have to spend not less than a quarter of a million sterling on printing and other telegraph machinery in telegraph offices.

* Abstract of a Paper read before the Institution of Electrical Engineers.]

Digitized by Google

PART II.—(DIFFICULTIES IN GENERAL).

The printing telegraph inventor has to conform to most intricate and unexpected conditions, and although the telegraph administrations do all they can to assist in the development of printing telegraphy, they are still bound to look at the matter from the financial point of view, and to insist on a printing telegraph showing either (1) a saving of labour, or (2) a saving of line, or (3) a saving of time in transmission, or if possible all three. In fact, we may say that the difficulties in the way of introducing printing telegraphs are essentially commercial.

In Europe, excluding Russia, labour saving is most important, especially as the telephone has cut into telegraph traffic to such an extent that during the past few years the growth of telegraph traffic in most European countries has been small or nil. In giant new countries with magnificent distances, including the United States of America, Russia, Canada, South Africa, the Argentine, Brazil and Australia, the saving of wire is of the greatest importance, and some waste of labour may be tolerated if there is compensating line saving. In each case the relative advantages of line and labour saving have to be balanced to get the maximum benefit.

The difficulties in the way of labour saving in telegraphy may be roughly classed under two heads: those in connection with commercial messages and those in connection with press messages. Commercial messages are short and average about 20 words; constant stoppages of the mechanism are therefore necessary. With a page-printing telegraph the loss of time in cutting up tape and pasting it on message forms is saved, but provision has to be made and time allowed for line-feed, column-feed and page-feed. These delays take place every 20 words or oftener, thereby considerably reducing the saving possible in theory. The position is entirely different in the case of the stock-ticker and ticker news service, and practically the whole of the troubles are questions of mechanical maintenance.

Press Messages.—The conditions at the first glance are much more favourable for printing telegraphy, but actual experience shows that the obstacles are much worse than in the case of commercial messages. The British system of news distribution is divided into the Post Office "News Division" worked by the Wheatstone system, and the leased and private wires rented from the Post Office by the leading British newspapers. *London* is the great originating and distributing centre for news, and it flows out from London all over the United Kingdom. Taking first the Government service, in the British "News Division," news distribution is carried on by an elaborate arrangement of Wheatstone circuits, each message being perforated simultaneously on from one to eight tapes by pneumatic perforators, the tapes being then used to transmit press messages over as many as 30 different Wheatstone news wires, many of which have six or more towns strung on them in series. In this way news is distributed all over the United Kingdom at a very rapid rate, and with remarkable economy of labour, as one man can prepare a message for transmission to a hundred or more towns. There are very great difficulties in the way of any printing telegraph coming in and doing this work. In the first place, the news is distributed at a very high speed of from 200 to 300 words per minute. No printing telegraph can work steadily at such a speed on one wire. Also the Murray automatic system, and, indeed, any other printing telegraph using a special alphabet (not Morse), would require a piece of news to be handled in the Murray alphabet as well as in the Morse, unless the whole news service of Great Britain was handled entirely by the Murray automatic system. Apart from the speed difficulty and the cost of the apparatus, it would take years for a printing telegraph to be installed all over the country. Using it for a few circuits for news would mean double labour in perforating the messages, and although the advantages might be great enough to compensate for this extra labour the speed of the line would have to be dropped to about 150 words a minute.

In those countries where there is no highly complicated arrangement for news distribution there is no obstacle to the use of such printing telegraphs as the Murray automatic; but in countries where there is no complicated news-distributing organisation there is very little news traffic, and it can be handled easily by the Hughes and other low-speed and therefore cheap instruments.

Another difficulty about news work is that in London and other large centres of population at least 12 copies are required of press messages for the various newspapers. It puts a serious strain on any operator to make 12 copies continuously for long periods of time at high speed. Rotary mimeographs and hectographs get over the difficulty in New York, and there is no reason why they should not do equally well in London.

Newspaper Private Wires.—In the case of these wires the conditions for the most are even worse from a printing telegraph point of view. High-speed printing telegraphs are of necessity complicated, and require good mechanical skill to keep them in order. This means that a skilled mechanic with an assistant and a small workshop would have to be installed. The question of speed also is just as serious with newspapers as with the Post Office. Take, for instance, a great provincial daily paper like the "Glasgow Herald." Every night it sends from 30,000 to 40,000 words from its London office to its Glasgow office 400 miles away. The great bulk of this news is sent over the "Glasgow Herald" private wire between 5 p.m. and midnight, and the conditions are such that it is absolutely imperative to have a speed of transmission over the line of not less than 250 words a minute (1,500 letters) and preferably 300. At present the work is done by the Wheatstone system, and there is a staff of six to eight operators in London, who punch the news in the form of perforated tape, and it runs through the Wheatstone transmitter at 200 to 300 words a minute, coming out in the Glasgow office of the "Herald" as dots and dashes on a tape, which is then copied out by a staff of 8 to 10 men. It is not apparent how any printing telegraph can meet such requirements. The writer tried it with the Murray automatic system, but the utmost that he could achieve was 184 words a minute, and even this was with very fine adjustment, much too fine for practical work; 150 words a minute was practical, but it was too slow. Less serious troubles are to be found in the fact that mistakes show up badly in the type-written pages produced by printing telegraphs, and make the sub-editors uneasy about the accuracy of the messages. In the case of the Wheatstone the transcribers correct the errors as they proceed, and they write out clean "copy."

In spite of the great difficulties in the way of using printing telegraphs for news work, it would be taking too pessimistic a view to say that printing telegraphs cannot be used for press despatches. They can be and they are so used. In Germany and France, for instance, where the newspaper telegraph traffic is small, all the press messages are sent over the Hughes and Baudot printing telegraphs, and even in Great Britain printing telegraphs will in time make their way for news work; but it will be a very slow progress and very costly. The apparatus will have to be faultlessly made, and well-trained men employed to run it. There will probably be a saving of time, but the saving of labour will not be great.

The difficulties in the way of making a copy for record of telegrams delivered are explained, and the author points out that wet-press copying is the only practical method when printing telegraphs are used. The necessity for keeping copies of telegrams at all is not obvious.

When page-printing telegraphs are used a change is necessary in the telegraph forms used by various Administrations. There are two kinds of telegraph messages, those sent from city A to be delivered in city B, and those sent from city A to be re-transmitted in city B to city C. In city B nearly all telegraph administrations use two different kinds of telegraph forms to distinguish these two kinds of messages. For a page-printing telegraph only one form for both kinds of messages is possible.

Numbering messages involves a waste of about 2½ per cent. in line time and labour; and the tendency is to omit all unnecessary signals. Whether consecutive numbers on telegrams are necessary appears to be an open question. Certainly numbering is a safeguard against messages being lost—an accident that happens occasionally in all telegraph offices. Hence when the Murray automatic system was introduced into the British telegraph service it was considered desirable by the officials to resume the numbering of messages on the Murray circuit. This is a small matter, but it involved a certain amount of change of routine, and in a big department a change of routine is a matter of difficulty. The experience of the writer is that the real conservatives are not the official heads but the operators, who often show extraordinary reluctance to accept change of routine. In fact, that is one of the minor obstacles to the introduction of printing telegraphs.

Counting the number of words in telegrams is a serious matter, causing much waste of time and labour. Charging by the number of words is a very defective system, but it is difficult to say what better arrangement could be adopted. As long as word counting remains in force it will be one of the hindrances to any considerable saving of labour by printing telegraphy. The number of words in the message is sent in the preamble, and it is the duty of the receiving operator to count the number of words in the received message to see that it agrees with the number in the preamble. In case of discrepancy this involves a talking back and forward, which, with printing telegraphs, is not so quick as with the Morse key. There are also so many Siamese twin words that are neither one nor two that counting is difficult, and the labour cost is increased. Thus, "motorbus" is one word, but "motordriver" is two. If it were possible to charge for telegrams in some way by time as in the case of the telephone a lot of delay and labour would be saved.

Apart from these difficulties, the most serious trouble a printing telegraph system has to face is errors in telegrams. These, due to

Digitized by Google

disturbances on the telegraph line, stray currents, inductive interference, men repairing the line, wind and weather, or to the human operator, involve repetition of messages and impose very serious limitations on the time and labour saving possible with printing telegraphs.

A special difficulty for printing telegraphs is also to be found in the variety and irregularity of telegraph traffic, which varies greatly in volume and in character according to the circuit and the seasons. There are also great variations in the volume and kind of traffic according to the hours of the day. Moreover, the present system of multiple address messages is impossible with a printing telegraph.

Traffic arrangements and hours of duty of operators are necessarily of a very complicated character in the case of large telegraph administrations, and the introduction of printing telegraphs leads to considerable variation of these arrangements. It is most difficult to introduce changes in the daily routine of large numbers of human beings. Of course, in the case of France, Germany and other countries on the Continent of Europe, where the Hughes has been largely employed for more than a quarter of a century, such difficulties have long since adjusted themselves. It is in the Morse key and sounder countries that the introduction of printing telegraphs necessitates some changes of routine.

International telegraph traffic presents special difficulties because of the division of authority and difference in habits and ideas and customs, and differences in language. Alphabetical troubles are not the least that printing telegraph inventors have to encounter. Each country requires some variation in the telegraphic alphabet, and it appears to be a physical impossibility to devise a printing telegraph that will suit all languages. A curious illustration of this alphabetical difficulty is the confusion that exists in Great Britain through the use of the oblique stroke both for money and fractions. 3/8 may be read as 3s. 8d. or as $\frac{3}{8}$. This confusion has led to monetary loss. Code and cipher messages also are the despair of telegraph administrations, but on the whole a good printing telegraph can handle such messages with less risk of error than the Morse key and sounder, and at least as expeditiously if proper methods are used. The essential condition is careful training of operators in working on typewriter keyboards without looking at the keys.

The use of envelopes and the addressing of telegrams present difficulties in the case of page-printing telegraphs. On the Continent of Europe envelopes are not used, and the telegrams have to be folded up in special ways, varying with each administration. The printing of the messages must suit these methods of folding. This requirement is hard to fulfil in the case of a page-printing telegraph.

Finally, there are mechanical difficulties of construction. Printing telegraph machines belong to a theoretically bad group of mechanisms, in which the majority of the actions are striking instead of liding or rolling, and it is only by close attention to details that uccess has been achieved.

(*To be concluded.*)

NEW METALLIC FILAMENT LAMPS.*

BY G. S. MERRILL.

Summary.—The author discusses the physical properties of the filaments of incandescent lamps. A description is given of the apparatus used for testing the breaking strength of metal filaments, and the effects of burning on continuous and alternating current circuits are shown for tungsten lamps.

The author deals with the lamps themselves rather than with their applications in commercial service, and discusses the following physical properties of the materials: Electrical resistance, vapour tension and melting point, emissivity, selectivity, mechanical strength.

The following figures are given for the effect of 1 per cent. increase in voltage of lamps operating at normal efficiency—

	Increases wattage.		Increases c.p.
Tungsten	1·59 per cent.	....	3·73 per cent.
Tantalum	1·72 per cent.	....	4·27 per cent.
Metallised carbon	1·77 per cent.	....	4·90 per cent.
Treated carbon	2·07 per cent.	....	5·69 per cent.
Untreated carbon	2·32 per cent.	....	7·10 per cent.

The filament of an incandescent lamp must not only meet certain requirements of an electric conductor but it must also possess certain characteristics as a luminous radiator. The latter condition greatly limits the number of materials which can be used as filaments of incandescent lamps. The light of incandescent lamps is produced by temperature radiation as distinguished from luminescence or fluorescence. It is therefore desirable to operate the incandescent filament at as high a temperature as possible in order that the proportion of the energy radiated within the visible spectrum, and hence the efficiency of light production, may be high. The maximum temperature at which it is possible commercially to operate a certain material in the high vacuum of an incandescent lamp bulb is determined by its rate of disintegration if the vapour tension is high, and by its melting point if the vapour tension is low. The high vapour tension of the carbon filament, which is shown by its tendency to evaporate at temperatures far below its melting point, makes it impossible commercially to operate carbon filaments at the normal working temperature of the tungsten filament.

Not only do the various filament materials differ in their ability to withstand high operating temperatures, but they differ also in their radiating properties. The emissivity or more ability to radiate energy does not affect the luminous efficiency, but it plays an important part in determining the lengths and diameters of filaments in commercial lamps.

The metal osmium has been shown to possess the property of selective radiation in the visible spectrum to a high degree, but the difficulty of working it and its relatively low melting point have made its commercial use impracticable. Tungsten, while not quite as selective as osmium, is more plentiful, and moreover it can be operated commercially at a higher temperature and efficiency, so that it is a more a desirable filament material than osmium, in spite of the greater selectivity of the latter substance.

The greatest problem in the production of metal filament incandescent lamps has been to produce the filament material in a high state of purity and in the proper physical form, and the ingenuity of the manufacturer has been taxed to the utmost in devising means by which this can be accomplished. It is difficult to secure a high degree of purity in tungsten metal, principally because its atomic weight is high and, in consequence thereof, a very little carbon (which is the most common impurity) is sufficient to form a considerable amount of tungsten carbide. The Paper contains a number of micro-photographs which illustrate the changes during the various processes of manufacture and during the subsequent burning. Microscopic inspection of the longitudinal surface of tungsten filaments after various periods of operation shows that a gradual wrinkling or breaking up of the surface takes place. Apparently the effect is confined almost entirely to the surface material, the filament itself suffers no serious distortion and no marked difference in appearance is produced by burning on alternating current. The appearance of the tantalum filament after burning on direct current is not very different from that of a tungsten filament, but on alternating current a gradual breaking up of the tantalum filament takes place. This can hardly be ascribed to vibration due to rapid heating and cooling, because tungsten filaments, operated under similar conditions do not show this tendency.

The study of the change in appearance of filaments throughout their life naturally leads to a consideration of the effect of burning on the strength of the filament. In order to investigate the relative strength of lamps of different types, various methods of testing them have been devised. Strength tests are made with the filaments cold, because when they are heated it is practically impossible to break them, the most serious damage that can then result from shocks and blows being a twisting together of one or more loops.

One method of testing strength consists of mounting the lamp rigidly on a block which can be bumped by a second block allowed to swing as a pendulum. The impact is regulated by the arc through which the pendulum is allowed to swing, and is increased by small increments until the filament is ruptured. The method has been modified by one investigator so that the impact is obtained through a ball rolling down an inclined plane. Another method requires the lamp to be mounted on a block which can be dropped from gradually increasing heights, the apparatus resembling somewhat a miniature pile driver. Other tests have been made by packing lamps in boxes as for shipment, and dropping the boxes from increasing heights, the lamps being frequently inspected. These methods have the advantage of breaking the lamps under conditions at least approximated in service, and moreover give some indication as to the value of the method used in supporting the filament. The results obtained are at best somewhat erratic and a large number of lamps must be averaged in order to obtain a proper appreciation of relative strengths.

In order to obtain some idea as to the strength of the filament itself, considered apart from its supporting structure, several methods of testing have been commonly used. One method consists in laying the filament on a pad of paper, smooth but not rigid, and allowing a small metal cylinder to roll lengthwise along it. Rollers of increasing weights are used until the filament breaks. In another device the filament is drawn by a hook at the centre between two converging guides until it breaks; the distance which it was drawn into the

* Abstract of a Paper read before the Franklin Institute.

Digitized by Google

"I" before breaking gives an arbitrary measure of its elasticity. This method has been varied in another device so as to draw the filament through a spiral guide, thus giving the sample a greater and greater curvature until it breaks.

The number of ways in which filament strengths can be measured with precision is somewhat limited by the physical nature of the filaments and by their extremely small diameter. The filaments readily lend themselves to cross-bending tests, and in order to carry out certain investigations a device for making such tests with some degree of accuracy was constructed. Short pieces of filaments were supported at points 0·5 cm. apart and a load slowly applied at the middle until the filament broke, the load and deflection both being measured. By taking short pieces of filament it was possible to test from 10 to 20 samples from a given lamp, and the average load and deflection shown by these 10 or 20 samples gives a very good measure of the filament strength in that particular lamp. In addition to determining the breaking strength, the deflection under various loads could be measured and deflection load diagrams could thus be obtained.

The machine, which it is believed involves a new principle, consists essentially of a horizontal beam balanced on a knife edge (*see* fig. 1), supporting at one end a cylindrical plunger C and at the other end a cylindrical weight W of the shape shown. The weight W at one end of the beam hangs with its lower edge midway between the points of support of the filament which is laid horizontally across an opening 0·5 cm. long. The block A carrying the filament can be raised through measured distances by means of a micrometer screw.

A small concave mirror, M, on the beam reflects light from the source to form an image at I. By keeping this image on a certain point, the beam may be kept horizontal and the deflection of the filament may be read from the micrometer screw.

The plunger at the other end of the beam hangs within a vessel which may be filled slowly with water. The plunger is buoyed up by the water as the latter rises and a load proportional to the weight

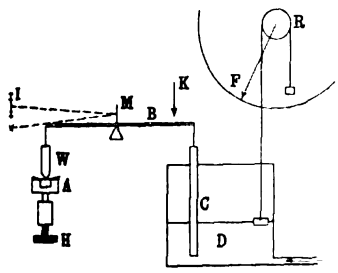

FIG. 1.—FILAMENT TESTING MACHINE.

of water displaced by the plunger is thrown upon the filament. As the plunger is uniform in section, the volume of water displaced can be most easily measured by its height upon the plunger. In testing, the beam has been kept balanced with a small part of the plunger submerged, and consequently the load upon the filament is determined by a difference in water levels. To enable the water level to be read with accuracy, a carefully balanced float rides upon the surface of the water in vessel D, and by means of a silk thread passing over the small pulley, R, its motion is magnified by the long pointer F travelling over an arbitrary scale. The water level readings can be reduced to the equivalent load in grammes on the filament by means of a calibration curve.

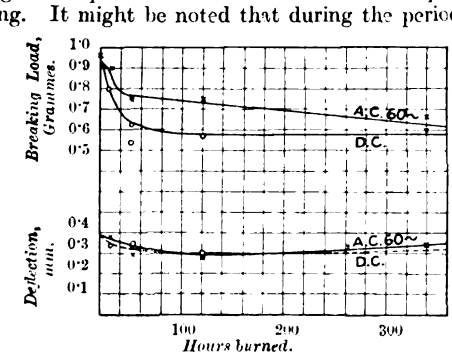
After putting the filament in place, and taking the initial reading of the pointer F and the micrometer head H, water is allowed to flow into the vessel D. As this throws a load on the filament and produces a deflection, the operator raises the filament with the micrometer screw, in order to keep the image I at a fixed point. The reading continues until the filament breaks, at which instant the water supply is automatically cut off by electrical contact of the unbalanced beam with the point K. The pointer F indicates the water level at breaking. The deflection of breaking is indicated by the difference between the initial and final readings of the micrometer head.

In order to compare strengths and deflections of filaments of varying size, it was necessary to express the results in terms of some unit length and diameter. Consequently all measurements of strength and deflection have been reduced to the equivalent load in grammes and deflection in cm. of a filament 0·5 cm. long and 0·005 cm. in diameter. In some cases filaments were found to be slightly elliptical in cross section rather than circular. (The difference between the maximum and minimum diameter, however, rarely exceeded 10 per cent.) In reducing the results of the cross-bending tests to a common basis, the diameter of the filament was therefore taken as the mean of two diameters at right angles in order to reduce the error due to possible deviation from a circular section.

Some of the most interesting tests made with the device have reference to the change in strength of the filament during its life. Three lots of 40-watt 110-volt tungsten filament lamps representing modifications in manufacturing processes were run through such comparative test. Each lot was divided into two parts, one of which was burned on 60-cycle alternating current and the other on direct current. All lamps were burned at 1·23 watts per candle-power. At certain intervals lamps of each lot were removed from the burning racks and the strength of the filaments tested. Fig. 2 shows the results of the tests for one lot, the general tendency of the curves being the same in each case.

Each point on the curves is the average of 10 determinations of strength of the filament from a single lamp. The deflection at breaking indicates that the flexibility of the filaments does not change very much with burning, especially after the first few hours.

The decrease in strength with burning could be most easily shown by either some change in the structure of the filament or by some change in the effective cross section. Although the results have all been reduced to terms of a uniform gross diameter, a microscopic inspection of the filament shows that there is a tendency for the surface to become wrinkled with burning, which would, in all probability tend to reduce the effective diameter as far as strength is concerned. In general, the surface which was originally smooth gradually becomes rough during the first 100 hours burning. Beyond this point the changes are not so marked. The strength curves indicate in a general way that the greatest reduction in strength occurs during the first 100 hours of inspection, and thereafter the change is less marked. This seems to point to the possibility that the strength is dependent at least to some extent upon the surface roughening. It might be noted that during the period covered by



Results reduced to filaments 0·5 cm. long, and 0·005 cm. in diameter.

FIG. 2.—CURVES SHOWING STRENGTH AND DEFLECTION OF TUNGSTEN FILAMENTS.

the test the gross diameter of the filaments of the several lots remain practically constant, *i.e.*, no marked reduction in diameter with burning could be noted.

In regard to changes in structure, there is a tendency for the crystalline structure to become somewhat coarser with burning. This change would naturally tend to weaken the filament due to the greater ease with which the fracture could follow the larger crystalline surfaces. A compact small-grained crystalline structure is apparently the more desirable from the standpoint of strength. The investigation, however, should be carried further before any definite conclusions are reached.

In order to give the relative idea of the strength and stiffness of a tungsten filament and a glass thread, a glass rod was drawn down to a diameter approximately equal to that of the filaments and a number of samples were tested. The ultimate strength of the threads of glass was almost three times that of the filament, but the flexibility of the glass was considerably less, giving about 60 per cent. as great a deflection as a tungsten filament under the same load.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

(ONLY ADDRESS.)

Tel.: Holborn **6363** (Two Lines). *Tels.:* ELECTRICIAN NEWSPAPER LONDON.

All Letters relating to Subscriptions, Advertisements and other business matters to be addressed Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-st., London. Cheques and P.O.s to be crossed "Coutts & Co."*

All Editorial communications to be addressed to THE EDITOR. *Letters for insertion in* "THE ELECTRICIAN," *or containing questions, to be accompanied by name and address of the writer as evidence of good faith. No notice is taken of anonymous communications.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers,* **and has an influential circulation all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office at latest by Wednesday evening's post. Renewals of expiring Advertisements and alterations to standing Advertisements by first post Wednesday. Wrapper Advertisements by first post Wednesday.*

CONTRACTS *and other* OFFICIAL ANNOUNCEMENTS, AUCTIONS, APPOINTMENTS VACANT AND WANTED, *and all kinds of* SMALL ADVERTISEMENTS *accepted up to* **3.30 P.M. Thursday.**

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPEOIAL NOTICE.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

BATTERY ECONOMICS.

Mr. A. M. TAYLOR's persistent advocacy of accumulators as a desirable adjunct in large as distinct from small generating stations is evidently bearing fruit and causing other engineers to think more about this problem. At the last meeting of the Institution of Electrical Engineers, Mr. TAYLOR read another Paper dealing with the same subject, though more from the point of view of using a battery to the best advantage as regards its efficiency.

A battery differs from a dynamo in that the E.M.F. falls with a heavy discharge in addition to there being internal drop due to resistance. A battery therefore acts like a dynamo having a large demagnetising armature reaction; but unfortunately there is nothing to correspond with the exciting coils in a dynamo for bringing the E.M.F. back to the desired value. This feature makes efficient regulation difficult. As is well known, two methods of compensation have been used; one being by means of regulating cells, and the other by means of boosters. Leaving out of account buffer batteries, to which our remarks do not apply, regulating cells are found to give sufficiently quick regulation, but they have the well recognised disadvantage that

Digitized by Google

these end-cells are put to very unequal use and that deterioration consequently results. The construction of sliding contact switches when the currents to be handled are heavy also presents a difficulty; but, nevertheless, this method of regulation has been used largely both on the Continent and in the United States, even when the currents have been as high as 40,000 amperes.

Practice in this country, on the other hand, has favoured the booster, which in this connection may be regarded as a home product. Here the difficulty is of another kind. If a battery is to be used for dealing with peak loads in preference to the installation of further steam plant, the question of efficiency becomes important. When a booster is used for regulating the discharge of a battery, energy is being used for this purpose just when all the energy available should be sent into the feeders. Moreover, the booster under these conditions is very often run inefficiently, being worked for a large part of the time at considerably under full load. It is for these reasons, no doubt, that very low overall efficiencies are sometimes obtained, a figure of only 54 per cent. being mentioned by Mr. A. H. Seabrook during the discussion on Mr. Taylor's Paper.

The solution proposed by Mr. Taylor in order to raise the efficiency is to run three boosters instead of one, the boosters being run three in series when the E.M.F. required is a maximum and the current a minimum, and three in parallel for the converse conditions. At first sight these may seem complicated arrangements, but there is no particular reason why they should not work out fairly simply. From an efficiency point of view the booster is certainly a weak point in this method of regulation, and anything that can be done to cut down the size of machine that must be used should materially improve the conditions. Something more might also be done on the lines pointed out by Mr. Taylor, namely, so to proportion the battery that at times of lowest load it could be run without any booster in circuit.

There is little doubt that large batteries of accumulators have certain distinct merits or they would not be used to the extent they are in other countries. This may be due partly to the fear of heavy penalties in the case of failure to supply, and this point of view seems to apply in the case of German stations. But we doubt if this is so in the United States, where, nevertheless, many very large batteries are in use and where end-cells seem to be favoured. Actual results obtained in practice are more valuable than any estimates of what may happen, and we do not doubt that the figures given by Mr. S. L. Pearce during the discussion on Mr. Taylor's Paper will produce considerable effect on those who are considering the economics of the question. The figures obtained at Manchester, namely, a commercial efficiency of 71 per cent., including losses in boosters, for a period extending over one year, is an extremely fine result, and serves to show that the efficiency obtainable depends considerably upon the conditions of working. Mr. Pearce also mentioned, as will be seen elsewhere, that the average saving in coal amounted to 13 per cent., and that the loss of energy in the battery was covered four times over by the coal saved. Having regard to these results, and to the fact that battery makers will give terms of maintenance extending up to 15 years, it is to be hoped that the Local Government Board will now take a more rational view of things and will grant longer terms than seven years for the repayment of battery loans, for these terms can only act as a deterrent to municipal engineers wishing to adopt accumulators on an extensive scale.

REVIEWS.

(Copies of the undermentioned works can be had from The Electrician Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Die unipolare Gleichstrommaschine. By Boris von Ugrimoff. (Berlin: J. Springer.) Pp. 98.

The unipolar machine has always been a fascinating subject to the electrical engineer. Yet in scarcely any branch of his work, has his labour been less rewarded or his task more thankless. Indeed the production of a continuous current from a machine without a commutator seems ever to have been one of the alchemist's riddles in electrical engineering, and the number of untold hours—apparently wasted—on this alluring subject must be appalling. True, certain practical forms of the unipolar machine have been developed and are in use, but up to the present this type does not appear to have any market value.

The present booklet is a thesis on the unipolar, continuous-current generator, and was submitted as a "Doktorarbeit" to the Technische Hochschule, Carlsruhe-in-Baden. In the first 38 pages the author deals with the development of this machine, and gives a general historical survey of the subject from its earliest days down to the latest improvements. After describing the methods used for giving this machine practical shape, the author passes on to consider the contact made between a rotating disc and quicksilver. A long series of experiments is described with different arrangements of this liquid contact at very high peripheral speed. It is only when water-cooling is resorted to, however, that a practical solution can be found. The theory is then evolved by the aid of hydrodynamics.

On the basis of these investigations a machine was designed to give 80 kw. at 40 volts when running at a speed of 8,000 revs. per min. It is difficult to express an opinion on the results obtained from an experimental machine of this kind, but of the author's own conclusions we may mention the following:—

1. The unipolar machine with nickel-steel disc armature and good liquid contacts can be made to yield pressures sufficient for incandescent lamps.

2. The water-cooled liquid contact has proved satisfactory for collecting current at peripheral speeds up to 270 metres per second.

It is not often that the thesis for a doctorate leads to the development of a new type of machine, and we shall be glad to see with what success the author's future investigations are attended. S. P. S.

Compulsory Working and Revocation of Patents. By Ernest Lunge. (London: Stevens & Sons.) Pp. vii. + 89. 3s. 6d.

No part of the Patents and Designs Act of 1907 has been the subject of so much discussion as Sec. 27, which re-introduced into English patent law the principle of "compulsory working" the principle that an inventor who holds a British patent shall put his invention (even though it should be for a minor improvement on some existing machine or piece of apparatus) into practice in this country under pain of forfeiture. The controversy is still going on; one side lauding the section in question as being the essence of legislative wisdom, the other denouncing it as highly unjust towards inventors, a most useful and deserving section of the community. The subject is still further confused by introducing political issues into the controversy, and the only fault we can find in Mr. Lunge's excellent monograph on the compulsory working of patents is his little digression into the Free Trade and Tariff Reform

Digitized by Google

controversy. We suppose this is pardonable, as compulsory working is, as Mr. Lunge clearly shows, a revival of a practice of the 17th century when monopolies, tariffs, &c., were hotly debated. We believe that we should have been able to make out a good case for a modification of Sec. 27 of the 1907 Act without having recourse to current political controversies. However, the blemish is a small one, and we can heartily recommend Mr. Lunge's book as being a complete and accurate guide to the law and practice relating to the compulsory working of patents in this country. Both the State (which grants the monopoly for working an invention) and the patentee have an interest in the subject-matter of the patent, and we think that Sec. 27 of the 1907 Act is too rigid, too sweeping in its character, and we believe that time and experience will prove this to be so.

The Young Electrician. By HAMMOND HALL. (London: Methuen & Co.) Pp. xvi. + 289. 5s.

The author states in his preface that this book pretends to no higher aim than that of affording instructive amusement to intelligent boys. We are afraid, however, that, except in the case of a few geniuses, the majority of boys will find much of the contents too technical. In fact, the volume savours more of an elementary treatise on electricity and magnetism, many of the diagrams (especially those relating to dynamos and motors) being more suited for a text-book. Apart from the large number of technical terms, such as "inductive capacity," which have been introduced, the author would, we think, have been better advised to have omitted such appliances as the "Prony brake" and the names of all except the best known scientists. Thus, few electrical engineers would be familiar with the name "Lesage," who, we are told, suggested a machine for spelling out words by means of pith-balls; nor would they connect the name Henley with a discharger for a Leyden jar. Again, it is scarcely necessary to mention in a book of this kind that the telautograph was invented by Elisha Gray.

The subject of electricity possesses a fascination for most boys, and no difficulty should be experienced in arranging a large number of experiments requiring very simple apparatus that would familiarise the naturally inquisitive mind of a boy with the general features of electricity. The present volume, however, errs on the side of "over-completeness," and may possibly confuse by the mere wealth of material.

RECENT PHYSICAL RESEARCH.

VII.—MAGNETIC BODIES COMPOSED OF NON-MAGNETIC ELEMENTS.

BY D. OWEN, B.A., B.SC.

§ 1. Heusler's discovery in 1903 of the magnetic alloys of copper, aluminium, and manganese opened the way to a new line of physical investigation. For the first time elements which alone are very feebly magnetic were seen to be capable of forming, when in combination, a ferro-magnetic body. The question arose as to what limits of intensity of magnetisation were possible in this new class of bodies, and whether they might not exceed the saturation value for the most magnetic of the ferro-magnetic group of elements—namely, iron. The practical consequences of such a consummation are too obvious to be enlarged upon. Whilst it cannot be said at present that these hopes are in any way realised, neither can the new facts be said to have received as yet any adequate explanation, and the experimental side of the subject appears to be far from exhausted.

Of the large number of investigations already made may be specially mentioned those of Fleming and Hadfield, of Prof. Gray and other workers in the Glasgow University Physical Laboratory, of Wedekind, and of Bruce V. Hill, as well as of Heusler and his co-workers. An account of the main results follows below.

§ 2. *Heusler's Alloys.*—Heusler succeeded in producing a number of ferro-magnetic bodies containing copper and manganese along with a third metal which might be Al, As, Zn, Sb, Sn, &c. Of these the alloy containing aluminium gave the best results. A systematic study of the effect of variation of composition led him to the conclusion that, for any given percentage content of copper, the alloy is most magnetic when the aluminium and manganese are present in the proportion of their atomic weights. Maintaining this proportion, the magnetic quality improves as the percentage of copper diminishes. This reduction cannot, however, be carried below 60 per cent., owing to the unsatisfactory mechanical qualities that the product then manifests. Alloys containing more than 60 per cent. of copper are amenable to working on the lathe, though forgings are not possible.

Confining attention to the properties of the copper-aluminium-manganese alloy, with percentages 63·5, 12·5 and 25 respectively in the order named, an examination of the results of different observers shows considerable differences, which appear to be largely attributable to differences in the thermal treatment undergone by the test specimens. For the moment let it be said that these thermal effects are very decided, as well as complicated. This alloy may, however, be broadly classed with nickel and cobalt and the medium grades of cast iron. It gives the well-known general form of **B-H** curve, with **B** = 3,000 to 5,000 for **H** = 150, with a maximum permeability of some 200 occurring at low field strengths (less than 10 C.G.S.).

The *coercive force* is rather greater than for nickel or cobalt, and consequently the hysteresis is greater. According to Fleming, the latter may be represented by a formula of the Steinmetz form—viz., $W = \eta B^{n}$, the power of **B** required being about 2·25. The value of η found for a specimen containing 60 per cent. copper was 0·000549, and for one containing 68 per cent. Cu 0·00077.

These alloys possess a critical temperature, or temperature of magnetic transformation, varying between the limits of, say, 250°C. and 450°C., according to percentage composition. Cooling curves indicate the evolution of heat in passing through that point.

The effects of *thermal treatment* are very marked, but are not capable of representation by any simple law. This is only to be expected in view of facts that are well known as to the behaviour in this respect of other magnetic compound bodies. Thus, for example, the so-called non-magnetic manganese steel containing 12 per cent. of manganese is capable under certain treatment, of becoming distinctly magnetic again, Hopkinson's nickel-steels are capable of existing in two distinct states, both stable at the same temperature, one magnetic, the other practically non-magnetic. Beginning with a Heusler alloy which has been cast and cooled down more or less slowly from the melting point (between 900°C and 1,000°C.) to ordinary temperature, it has been generally found that an improvement in magnetic quality (to the extent of an increase of some 30 per cent. or more in **B**) is obtainable by a process of "ageing," the specimen being maintained at a temperature of about 110°C. for several days, then tested at room temperature. Subjection to higher temperatures results in a deterioration to an extent greater as the temperature is higher. The experiments of Hill on this subject are especially valuable. He found a temperature of magnetic transformation of about 330°C. for the specimens investigated. As cooling took place from this point the magnetism steadily increased though on regaining room temperature the intensity of magnetisation was only 250, a distinct drop on the initial value of over 300 (field kept steady at 85 C.G.S.). A second heating this time up to 500°C., was carried out. On re-cooling the magnetisation regained was very small—namely, **I** = 27 at 17°C. Further cooling to −190°C. only increased **I** to 36. It is thus possible to obtain the alloy in two states: one strongly magnetic, the other comparatively feebly magnetic, at the same temperature. This is the phenomenon already observed in the case of the nickel steels by John Hopkinson. But in the manganese alloy the magnetic condition is not restored at a lower temperature. It therefore occcurred to Hill to observe whether a rise of temperature, to a point considerably above the temperature of magnetic transformation, would result

Digitized by Google

the passage to the magnetic state. This he found to be the case. On heating to a dull red heat (650°C. to 700°C.) and allowing to cool slowly the value I=90 was found at 17°C. H. Sh. On then heating to bright red heat (say, 850°C.) and allowing to cool the value I=155 was obtained at room temperature. The Heusler alloy is, therefore, irreversible as regards variation of magnetism with temperature. In contrast with the 25 per cent. nickel-steel, which appears in the non-magnetic condition on cooling from melting point, the cast Heusler alloy appears in the magnetic state. The changes are not, however, of so simple or definable a character in the former case as in the latter; there is no definite cycle which can be traversed over and over again (H constant) with precise return to one of two definite values of intensity of magnetisation at any given temperature. Like the nickel-steel, the Heusler alloy shows distinct differences in density, &c., in the magnetic and non-magnetic states.

The effects of very low temperature have been investigated recently in the Glasgow laboratory. At the temperature of liquid air the magnetisation is distinctly greater than at ordinary temperature. If the alloy has been rendered but very feebly magnetic by raising to about 300°C. and quenching in water, the magnetism is largely or entirely restored on cooling to −190°C. This increase of magnetism is not, however, retained on return to ordinary room temperature. The effect of extremely low temperatures, it may be noted, is in this respect opposite in sign to the effect recorded by Dewar and Fleming in the case of annealed iron and pianoforte steel wire, though of the same order as the change in unannealed iron or in hardened iron.

§3. The copper-aluminium-manganese alloy is the most notable of the class of bodies here under consideration. Others, however, have been prepared. Mention has been made of some discovered by Heusler, in which the place of aluminium is taken by another element. Heusler also showed that certain Mn-Zn and Mn-Al alloys possess appreciable ferro-magnetism. Wedekind has added to the list a considerable number of compounds of manganese, including the sulphide and compounds with B, Sb, P, As, Bi, N, &c., respectively. All these show distinct remanent magnetism after subjection to an intense magnetic field. The boron compound is reported to have a permeability one-sixth or one-seventh that of iron, whilst a flux density approaching to within 30 per cent. of the value of iron is stated to be attainable in the case of MnSb. These results appear to require confirmation.

There is but little evidence of the existence of ferro-magnetic bodies from which manganese, as well as iron, nickel and cobalt are excluded. Wedekind reports CrB to be magnetisable to a marked extent. Ross and Gray have made experiments upon alloys of copper and aluminium which indicate the possession of a permanent, though very feeble, magnetism after subjection to a strong magnetic field. According to these experiments, the permanent magnetism is more pronounced when the material has been quenched from a high temperature. Cooling in liquid air accentuates the effect. For example, in the case of an alloy of 95 per cent. copper and 5 per cent. aluminium, the annealed material showed a remanent intensity of 0·01 C.G.S. at 15°C. and of 0·091 C.G.S. at −190°C.; the quenched material possessed an intensity 0·029 at 15°C. and 0·110 at −190°C. Experiments on practically pure copper led to similar results. The slowly-cooled material exhibited no sensible remanence after subjection to a field of 3,000 C.G.S.; the quenched metal, on the contrary, gave a remanent intensity of 0·10 C.G.S. at 15°C. and of 0·27 at −190°C. The traces of iron present were estimated to be far too small to account for these results. On the other hand, experiments with a very pure specimen of electrolytic copper showed no trace of remanence. These results can, apparently, only be reconciled by assuming that the traces of iron present in the first case form with the copper a magnetic alloy of considerably higher permeability than pure iron.

§4. In spite of these recent extensions of our knowledge of ferro-magnetic bodies, the problem of their constitution remains unexplained. Iron in the pure state is strongly ferro-magnetic; in its salts it is paramagnetic, capable only of feeble magnetisation in comparison with the amount of iron present, and devoid of retentivity; in its alloys it may become, as in Hadfield's manganese steel, only feebly ferro-magnetic; in combination with aluminium or silicon its permeability may in low fields exceed that of pure iron, but on carrying the magnetisation to saturation the aluminium appears to function only as a non-magnetic diluent. Some of the nickel-steels may in one state be practically non-magnetic, in a second state more magnetic when saturated than a mere mixture of the elements present would be. Clearly, then, the magnetisability of a body is not a function merely of the atoms present, but depends on the structure of the molecule or on the manner of grouping of the molecules.

The interesting question of the part played by manganese is still an open one. Practically all the magnetisable bodies from which iron, nickel and cobalt are excluded contain manganese. Certainly all those of marked magnetic quality do. Does, then, manganese belong fundamentally to the ferro-magnetic group of elements, as Faraday considered probable? The nearness of its atomic weight (55) to that of iron (55·9) suggests it. It is curious that the black peroxide MnO_2 was for long known as *magnesia nigra*, on account of its supposed magnetic properties, the name manganese being thence derived to distinguish this element from magnesium. Metallic manganese as normally prepared is, however, non-magnetic. This commercially pure metal is, in truth, but a crude product, containing, it may be, some 4 per cent. of impurity, chiefly copper and iron. Weiss has produced the pure metal by electrolytic reduction of $MnCl_2$, using a mercury cathode and an anode of platinum-rhodium. The grey powder which results on driving off the mercury by application of heat in presence of hydrogen behaves, when compacted into a rod, as a paramagnetic body. Melted in an electric furnace in a vessel composed of magnesia and in an atmosphere of hydrogen it acts as a ferro-magnetic body. A BH curve was obtained showing an enormous coercive force (670 C.G.S.), with a remanent intensity one-hundredth that of pure iron. Even at H=12,000 the specimen still remained unsaturated. This manganese, furthermore, appeared to have strong magneto-crystalline properties. Such appears to be the most successful effort at producing elementary manganese in a distinctly magnetic state. Cooling experiments down to liquid air temperature have long since been made, only to negative the idea of a simple explanation in terms of a low temperature of magnetic transformation. The magnetic nature of the element has to remain for the moment unexplained.

BATTERY ECONOMICS AND BATTERY DISCHARGE ARRANGEMENTS.

We give below an account of the discussion that took place at the meeting of the Institution of Electrical Engineers last week, when Mr. A. M. Taylor read his Paper on the above subject. An abstract of this Paper appeared in our last issue.

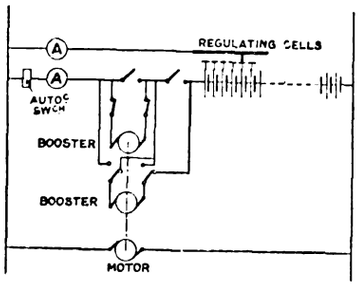
DISCUSSION.

Mr. TAYLOR, in reading the abstract of his Paper at the meeting, applied his figures (given in Tables B, C, E, F) to Fig. 19 of the Paper, showing the load at Dickinson-street. The area of the curve represented 93,800 units per day, or 33,800,000 units per annum—that is, a 35 per cent. load factor. They might compare the cost of putting in steam plant for the whole 11,200 kw. as against the cost of installing steam plant for 5,200 kw. and battery plant for 6,000 kw. (at a 1½ hour rate), which would supply a two-hour peak. The fixed charges for the 11,200 kw. plant at £3·89 per kilowatt per annum were equal to £43,500; and the "true" running costs at, say, 0·15d. per unit equalled £21,100, giving a total of £64,600 for the all-steam scheme. Considering next the battery scheme, they had as follows: 5,200 kw. of steam plant at £3·89 per kilowatt =£20,200 per annum; 6,000 kw. of battery plant at £1·58 per kilowatt, or £9,480 per annum, giving a total for fixed charges of £29,680 per annum. To this had to be added £21,100 for running charges, as for steam, and £1,200 for lost units in the battery and boosters, giving a total for the battery scheme of £51,980. But, as no margin was provided in the battery plant beyond that of the normal peak, it was desirable to provide a second battery (which might be of the Exide type), for use solely for emergency conditions, having a 6,000 kw. capacity for 1½ hours. This battery would add to the fixed charges a sum of approximately £6,300

Digitized by Google

per annum (6,000 kw. at £1·05), making a total of £58,280, thus giving a saving of £6,320 per annum over that of the all-steam plant. It might be mentioned that the sum of £43,500, given in the steam scheme for fixed charges, included £3,100 on the 6,000 kw. plant, representing stand-by coal, which was entirely saved on the battery scheme.

Mr. B. M. JENKIN thought one of the most interesting points was the comparison made between the ordinary battery booster and the author's suggested arrangement. That method of working might be carried still further, since the chief object of the battery was to give the maximum possible discharge when it was most needed. So long as a booster was used to assist the battery to discharge, some energy would be used in the booster when it was of most value for the load. The question of how the boosters could be switched to run either in series or in parallel was left rather vague in the Paper. Personally, he was unable to follow the reason for the complicated proposal made, and he did not think it was really necessary. The suggestion in Fig. 14 of a double commutator and single field for booster was undesirable, because one required to have independent control of the voltage of each booster. No complicated switch was needed, so far as he could see, but it was necessary to have each armature in a separate field. He suggested that the absence of the booster during discharge was the point to be aimed at, especially if the battery discharge was to be regarded as a standby. The arrrangement shown in Fig. 4 involved a great deal of switching and depended entirely upon the boosters during the battery discharge. The author suggested in that figure the use of regulating cells in addition to the booster, but did not mention how it was possible to overcome the difficulty of properly charging the cells connected to the regulating contacts. The speaker suggested that the better plan would be to use regulating cells on a battery with a sufficient number of cells to take the discharge. He outlined the following arrangement: The booster was placed in parallel with the regulating switch circuit as indicated in the diagram herewith. During



charge the whole of the cells were equally charged through the booster. The regulating switch was adjusted to suit the 'bus bar volts, and the booster voltage was adjusted to give the required charge and at the same time keep the current through the regulating switch circuit at zero. During normal discharge the same method was followed, so that all the cells were equally discharged. During the beginning of the discharge the booster was run inverted and the motor delivered current to the 'bus bars. At the end of the discharge the switch was on the end cell and the booster shut down. In emergency the heavy discharge was taken through the regulating switch circuit, and the booster was automatically cut out as the switch was moved to the end cell. The regulating switch circuit was available for emergency discharges at all times, and was not affected by the booster connections which might be set with armatures in series or in parallel, charging or discharging.

Mr. C. E. C. STAWFIELD (Wolverhampton) could hardly agree with the advantages of using batteries for standby purposes, and more particularly with the suggestion for putting in boosters to enable a battery to be discharged at a high rate. He could scarcely imagine that in this country conditions were likely to arise which would make a 5 minutes' discharge rate necessary. Even if such circumstances did arise he thought they would last considerably longer than 5 minutes. He thought that 1 hour would be the shortest time necessary for a discharge; and if they wanted to go beyond that, the capital charges in respect of boosters &c., would be greatly increased. As to regulating cells versus boosters, he had certainly been under the impression that the booster was the best and most economical method of charging and discharging a battery; but he was very much surprised to find when he recently had an opportunity of going through the Berlin Electricity Works that the opposite opinion was held on the Continent. The regulating switches in use in those works were really wonderful in their simplicity and certainty of operation. He saw one move over several contacts when carrying 4,000 amperes, and although that particular switch had been in service seven or eight years the contacts appeared absolutely new. He was assured that they had not required any repairing or renewal during that period. In regard to the cost of regulating switches, it did not appear to be any higher than the cost of the boosters. In the case of a battery giving 1,000 kw. for 3 hours he was informed that the cost of the regulating switch and connections, delivered and erected, was £1,050. The switch was capable of discharging the battery at the 1 hour rate at, he thought, 4,000 amperes without damage and without any serious sparking. He thought that there was very little doubt that the efficiency to be obtained by the use of regulating cells was very much higher than was possible with boosters. Further, as the author said, units were wasted in the booster at the time when they were most expensive to produce, whereas the units for charging were used at the time when they cost the least. The extent to which batteries were used by the Berlin Electricity Works was rather startling, compared with English practice. The figures given in the Paper, he thought, were rather on the small side. He was informed that the capacity of the batteries installed in Berlin was 35,000 kw. on the 2-hour rate, and that in case of breakdown they were capable of maintaining the whole supply of the city for a period of 2 hours. Why it had been considered necessary to make such a large provision in the way of batteries was, he understood, that they resulted in considerable economy in coal, which was expensive in Berlin. Further, the supply company was under very heavy penalties to the local tramways, to the underground railways and to the municipality in the event of any failure of supply. The batteries installed were an insurance against the heavy liability for breakdowns. Such a state of affairs, however, did not exist in England, and he did not know of any case where supply undertakings were liable for more than nominal penalties. Therefore, he thought the use of batteries could only be justified where they reduced the cost of generation. The advantage, however, was limited to their capacity at the two or three hour rate, and arrangements should not be made for dealing with heavier currents. He wished the author had given further details of the Exide cells. He understood him to say that they were suitable only for emergency purposes and not for regular use. If that was so he could not see why their use was suggested at all. The principal use for a battery was to carry over the periods of peak load, and either the battery was to be used daily to meet the peak load demand or it was not required at all. He was not able to follow the author's figures. The standing charges for 11,200 kw. per annum were given as £43,500; surely it ought to be something like half of that amount. Then £3·89 per kilowatt per annum would represent a capital expenditure of over £30 per kilowatt, whereas with modern steam plant the cost would be as low as £12 per kilowatt. The comparison made by the author was not, therefore, quite correct.

Mr. S. L. PEARCE (Manchester) said that as the author had referred in two or three places in his Paper to the large batteries installed at Manchester, a few facts and figures relating to the first year's working might be of interest. In the first place he would like to correct the statement that the coal bill had been reduced by some 25 per cent. That was true of three months in the summer of last year, but the average for the completed 12 months was only 13 per cent. Originally, when the battery was installed, it was intended to charge entirely from the traction 'bus bars, and to discharge only on the lighting peak loads. The capacity of the battery at the one-hour rate was approximately 3,000 kw. It was quite possible, and at times was found to be of very considerable advantage, to run the booster motors from the traction 'bus bars as an alternative to the lighting 'bus bars. Although intended normally to charge the battery from the traction bars and to discharge on the lighting bars, it was so arranged that both charging and discharging if desired could be done entirely on the lighting system. The year's experience had shown that the best results were obtained by keeping the battery entirely on the lighting system. Possibly the conditions at Manchester were ideal for a battery of that capacity. As most of them knew, they had a high-tension station at Stuart-street and low-tension stations at Dickinson-street and Bloom-street; the two latter for all practical purposes might be considered as one.* That gave a very flexible arrangement. Supposing they had very dark weather in the morning and took a more or less complete discharge out of the battery, the load at Stuart-street, which supplied principally the tramways and industrial undertakings, would drop 6,000 or 7,000 kw. during the dinner hour, say, 12 to 2, and it was, therefore, quite possible to get a very good charge through the sub-station into the battery again during that interval of time. The battery charging rates were accordingly arranged to be as high as possible—viz., 4,000 amperes normal and 6,000 as a maximum. The battery was then ready to meet the peak. The conditions at Manchester for getting more than one discharge per day out of the battery were more or less ideal. With regard to the savings effected, he had estimated that during the first completed year these were as follows: Coal, a reduction from 3·33 lb. to 2·89 lb. per unit generated, or a saving of 13 per cent., which for an output of 30,550,000 units meant a saving of 6,055 tons, or £3,348 in coal alone. Other savings in the works costs had been secured. They amounted in all to 0·064d. per unit, and taking the given output of 30,550,000 units totalled £7,762. Allowing for full capital and maintenance charges on the battery, so far as he could see there had been a saving on the first year of £3,041. That took no account whatever of any saving on capital charges of plant, and if they were prepared to admit that the battery at the one-hour rate could be fairly compared with the steam plant at Stuart-street, plus high-tension mains, plus converting plant at Dickinson street, the capital cost showed £13 per kilowatt for steam plant and £8 for the complete cost of battery, switchgear, &c., a difference of £5 per kilowatt. Taking 8½ per cent. on £5 and 3,000 kw. at the one-hour rate they arrived at a saving of £1,900, or, with the above-mentioned £3,041, a total of approximately £5,000. This figure did not differ materially from that given by the author in the Paper. They estimated further that the daily steam plant load factor in the winter would be increased from 32 to 43·5 per cent., and as a matter of fact they had averaged 47 per cent., with some days as high as 60 per cent. On p. 24 the author referred to a sufficient saving in stand-by losses on boilers and engines shut down to make the value of the coal so saved equivalent to the losses in the battery and boosters. The figures at Manchester were: Total units lost in battery and boosters approximately 700,000, equivalent to £870, and this loss was covered four times over by the saving of coal. With regar

* At Dickinson-street they had installed a large sub-station, which formed the connecting link between the alternating-current and direct current supply stations.

Digitized by Google

to the question of rapid discharge, perhaps the figures of the Tudor battery at Manchester obtained in actual practice might be of interest :—

8,400 amperes for 1 hour.
13,000 amperes for ½ hour.
17,000 amperes for 5 minutes.

On the question of switches to deal with high discharge rates for short periods, he assured them that the design and operation of the Manchester switches made him wonder how the Americans successfully dealt with a 47,000 amperes current. He agreed with the author's remarks that it was not advisable to put in batteries exclusively as a stand-by. A battery large enough to act as a substitute for peak load steam plant and to give economy of working which made it a sound commercial investment, had, in his opinion, all the "emergency" qualities necessary. He agreed with the author's suggestion that for ordinary commercial purposes it was quite good enough to put in a battery to buffer the demand in foggy weather. With regard to the booster equipment, he thought the author had done Manchester an injustice when he spoke about the booster plant being insufficient for discharging the battery at emergency rate. That was not correct. The boosters were three in number and collectively, when operated in parallel, were sufficient to give current corresponding to the five-minute maximum discharge of the battery at maximum boost. They were divided into three sets because they were partly required for the traction load, when two were operated in series, but at times of discharge on lighting the boosters were all in parallel. They experienced no difficulty in working with the "series parallel" arrangement. It was quite easily arranged; in fact, the diagram of connections of the Manchester battery which had been published showed very clearly the arrangement of the switchgear, and no complications were introduced. He did not quite appreciate where the economy of the author's booster proposals came in. Something might be saved on capital account, but the losses, especially on charge, would, he thought, be greater than with the ordinary booster arrangement. With regard to Fig. 15, it seemed to him a purely hypothetical case, and hardly likely to occur in actual practice. He suggested that the maximum discharge was always coupled with the question of maximum boost. A point interesting to engineers-in-charge of municipal stations was the question of loan periods for batteries. The Local Government Board would only grant loans on batteries for seven years, whereas the makers were prepared to give maintenance contracts for at least 15 years. He thought, therefore, the period might reasonably be extended.

Mr. A. H. SEABROOK (Marylebone) said he had considered the question of the use of batteries for some years. In going into the figures for additional steam plant for the Marylebone station the capital cost came out at £57,000 and the cost for storage batteries of 3,000 kw. capacity on the 1-hour rate £26,000, a considerable saving. He was able also to fix up a maintenance contract with the battery manufacturers for 20 years, but the Local Government Board only allowed 10 years as the loan period. The loan period for batteries ought, he contended, to be extended, especially considering the high scrap value. The efficiency of 71 per cent. mentioned by Mr. Pearce was, however, rather staggering. He found the overall efficiency, including boosters, &c., was 54 per cent.; 71 per cent. was undoubtedly exceedingly good. As to regulating cells, he did not think these could be passed over in favour of boosters quite so readily as the author thought. Regulating cells were used extensively in America and in Germany. It would be interesting to know if any one had figures relating to the working efficiency of regulating cells as compared with boosters. Battery makers during the past year or two had been prepared to include regulating cells in maintenance agreements. A point in favour of regulating cells was that they were more reliable than boosters. The booster was the weak link in the discharge arrangement. Moreover, switching was much less complicated with regulating cells.

Mr. LEONARD ANDREWS called attention to apparent discrepancies between the first items in Tables B and C. The capital cost of the extra 1,500 kw. of steam plant was given in Table A as being £19,500. Interest and sinking fund at 6½ per cent. on this sum would amount to £1,270, or £50 less than the amount Mr. Taylor had included in Table C for standing charges on the steam plant. The author made him (the speaker) responsible for the higher figure by quoting from his Paper of two years ago on gas engines, but he could find no justification in that Paper for the figure included of £1·91 per kilowatt of maximum demand, which, he agreed with Mr. Shawfield, was much too high. He concluded that the author had arrived at this figure by adding to the 6½ per cent. on the capital cost of the 1,500 kw. of plant, 25 per cent. for additional stand-by plant, and a further charge for increased labour and repairs—(Mr. Taylor: That is so). He contended that it was altogether erroneous to assume that the increased labour and repairs would be directly proportional to the maximum demand upon the generating station. If, for instance, the labour charges on an 8,000 kw. steam plant amounted to £5,600—the figure given in the speaker's Paper—and the maximum demand on the steam plant was reduced to 6,500 kw. by carrying 1,500 kw. of the peak load on batteries, he was of opinion that the maximum reduction it would be reasonable to expect on the labour and repairs item would be £350 per annum. He considered, therefore, that the standing charges on the steam plant should not be taken as being higher than

6½ per cent. on £19,500	£1,270
25 per cent. extra stand-by	318
Extra labour and repairs	350

This total being £1,938, or £1·26 per kilowatt of maximum demand instead of £1·91. With this amendment, and accepting Mr. Taylor's figures for the other items, he considered that the correct total fixed and running charges should be :—

	Fixed charge per kw. maximum demand.	Running charge per kw.-hour.
For steam plant	£3·2	..... 0·221d.
For gas plant.....	£2·98	..... 0·0825d.

These figures still showed that a very substantial saving would be effected by installing batteries to deal with the peak load, as recommended by the author.

Mr. MACGREGOR DUNCAN said, in regard to maintenance contracts for batteries, it would be interesting to know if the manufacturers were prepared to give the same terms for contracts for stations where the conditions were such that the battery could be discharged twice, or even oftener, per day as for stations where it would not be possible to discharge the battery oftener than once a day. Did they limit the number of discharges per day by the terms of the contract?

Mr. W. R. COOPER (communicated) thought that the extremely efficient result obtained at Manchester might be due partly to the conditions under which the battery was worked apart from the boosters. This view was borne out by the fact that a buffer battery worked more efficiently than a battery used under the usual lighting conditions. The higher efficiency of the buffer battery was doubtless due to the small range of the charge and discharge curves over which working mostly took place. The most efficient result was likely to be obtained by working over what might be termed the flat parts of the normal charge and discharge curves as far as possible, so as to approach buffer battery conditions.

Mr. A. M. TAYLOR, in reply, thought Mr. Jenkin's principal objection was the complication of the switchgear, but the suggestion on which Table A was prepared involved no switchgear that had to be touched while the battery was being discharged. As to the switchgear shown in Fig. 14, the two double-throw switches were mounted on a separate panel and were put up or down, as the case might be, when the discharge or charge commenced, and would remain in that position. They were independent of the panel switches that would control the boosters. A sudden overload of the boosters could be easily met by having an automatic switch which short-circuited the booster 'bus bars and at the same time wiped out the booster fields and broke the booster motor supply. The boosters could then be put in on a one-hour basis, and the supply was also left uninterrupted. The proposals in Fig. 15 were really given as applying to special cases, but even these involved nothing but turning over the selector switches at predetermined times and required no adjustments or skilled attention. Mr. Shawfield appeared to be surprised at the booster losses. The losses with ordinary boosters were undoubtedly very serious, and incidentally he was therefore not surprised at the figures quoted by Mr. Seabrook. If, however, boosters could be used of from one-third to one-tenth the size, and always fully loaded, both on charge and discharge, the losses would become unimportant. After all, the greatest loss was in the batteries. He wished the makers could give them batteries that would show an energy efficiency of over 75 per cent. They seem to stick at that percentage. With reference to Mr. Shawfield's remarks, Fig. 23 might perhaps give the impression that for every three units generated one was lost in the battery and two delivered to the 'bus bars. They had to deal, however, with a one-hour peak corresponding with a 4 per cent. load factor, and if the load factor were, for example, 80 per cent., the batttery was supplying roughly 1 unit for every 16 units generated at the station; but only one-third of that 1 unit was the actual amount wasted in the battery; the waste was, therefore, only one-third of one-sixteenth, or one-forty-eighth of the total units generated. As to the fixed charge of £3·89 per kilowatt per annum, that included stand-by charges and stand-by coal, and was divisible by the diversity factor, when applied to consumers. With reference to Mr. Shawfield's remarks as to the use of regulating cells, it would be seen, by reference to Fig. 13 of the Paper, that the effect of increasing the number of cells sufficiently to give the one-hour discharge without a booster involved the use of a booster, merely for charging purposes, whose kilowatt capacity was equal to or greater than that required for discharging purposes on the triple-parallel method. Why, then, spend a very large sum in regulator switches, and be unable to work the battery to its full extent, and involve additional risk in maintenance, when you had got the booster ready to hand for the discharge? He (Mr. Taylor) quite agreed that, with ordinary booster arrangements, it was a question as to whether the booster should be employed for the discharge: but with the triple series-parallel arrangement there should be no doubt whatever on this point. It was quite easy and cheap to protect the booster against overloads by an automatic switch which short-circuited the booster, and at the same time wiped out the booster field and cut off the power from the booster motor. This would permit of a one-hour rating being given to the boosters, and would still keep the battery solid on to the 'bus bars. The regulating switches which he showed in his diagrams were very few in number and were not really regulating switches in the ordinary sense of the term. They were merely intended to permit of the battery floating on the line during the early part of the day, when used purely for stand-by purposes, and were accordingly very cheap. He was very pleased to hear that Mr. Pearce found his battery giving such successful results, and Mr. Pearce was to be congratulated for his courage in putting in a battery instead of steam plant at a time when such a proposal was looked upon askance. The figure of £13 per kilowatt for steam plant, which Mr. Pearce quoted, was almost exactly the figure assumed in the Paper, and he thought it would be found that his figure of £3·89 for the fixed charges was justified. He could quite understand Mr. Pearce's efficiency being high, but 71 per cent. was undoubtedly very good for an overall efficiency. Mr. Pearce suggested that it was a good plan to spend plenty of money on the booster, but why put in a booster of 700 kw. capacity if the same work could be

Digitized by Google

done with a booster of 250 kw. capacity or even 66 kw.? Money should rather be spent in spare boosters, as these were the weak links. Mr. Pearce had installed three boosters, and said they would deal with the emergency load: but he had no stand-by for a breakdown. He quite agreed on the point of longer loan periods for batteries. He thought Mr. Seabrook would find that it was his booster that was the cause of the low efficiency. If they were working the battery at the one-hour rate, which was three times the charge rate, then during the charge they were calling upon the booster to give 20 per cent. of its volts at some periods and throughout to run at one-third its discharge rate, and it was only natural that the efficiency should be low. In Fig. 13 of the Paper each booster was continuously loaded both on charge and discharge at its full current rate; and its efficiency increased in proportion. With regard to Mr. Andrew's remarks, he apologised for apparently misquoting his figures, but he thought Mr. Andrews would find on further investigation that this had not been done. He had tried to tack Mr. Shawfield's figures for rates, taxes and insurance on to Mr. Andrew's figures for other standing costs. He was glad Mr. Andrews admitted that £3·22 might be correct. As regards another speaker's inquiry as to the Manchester battery, he believed he was right in saying that the Tudor Company had faced the question of two discharges per day and yet had not raised the maintenance rates above those of other makers for the one discharge per day. One of the battery makers at the Nottingham discussion stated that about 3,000 discharges could be got out of one battery, which would cover a period of about 10 years with a single discharge per day, and perhaps that was a good basis upon which to work. With regard to Exide cells, his proposal was to instal these as a second battery, to be called upon only in case of breakdowns, or to deal with fogs, &c., in fact, only as a pure stand-by.

ENGINEERING EDUCATION.*

BY J. A. EWING, C.B., F.R.S.

There are two great professions in which the fruits of scientific study and the methods of scientific thought are directly applied for the benefit of man. These two are medicine and engineering. In both of them science is the proper basis of practice, but in both we have to recognise as a fact of primary importance that the practitioner, to be even fairly competent, requires much more than a knowledge of science or even a habit of scientific thought. He must have profited by what may be broadly described as experience, not simply the experience which he acquires at first hand in his own attempts to carry out professional work, but such of the advantages of experience as it is possible to become possessed of by association with men who have already acquired it.

The sciences which form the basis of engineering have not only grown *pari passu* with the art itself, but between the two there has been a continuous and most beneficent interaction. Physics may be said to owe to engineering as much as engineering owes to physics. Many of the greatest advances in theory, notably in electricity, are direct fruits of the demands made by practice and of the facilities for research which arose through the development of practical appliances. I believe the same is true of medicine. There is no need to labour the point, but it is important, in relation to the question of training, to recognise that whereas both arts began with nearly pure empiricism, both are now so dependent on and so closely related to science that the days of empiricism are dead. The transition has been gradual, and it has been accompanied by a corresponding, or perhaps I should say a somewhat lagging, change in the conception of how a young man should be prepared for professional life.

The successful empiric was a man who had experience and who in general had also that practical intuition which comes neither from scientific studies nor from experience, the intuition which, even in a scientific age, is still a potent factor in the highest professional efficiency. To train an empiric the natural way was to set him to assist a successful empiric, to learn his trade by helping, by watching, and by imbibing such counsel as the man of experience might communicate. Accordingly, the early system of training, both in medicine and in engineering, was a system of apprenticeship and nothing more. Sent as an apprentice or "pupil" into the office of a civil engineer or into works, the young engineer was left to pick up practical knowledge as best he could, with no foundation of scientific comprehension, without system or guidance, and in most cases without even the personal contact with a successful chief which was a redeeming feature of medical apprenticeship. Even at the present day examples may be found of young men seeking to enter the engineering profession in this haphazard manner. But it is now at least widely, though not universally, recognised that no proper education for the engineer is to be obtained by practical pupilage or apprenticeship alone, and that the ideal training is one which comprises, in addition to means of getting experience, a properly organised course of study in the relevant sciences taught with reference to their practical application. These "applied sciences" may be broadly described as the theory of engineering.

The Institution of Civil Engineers has done a good deal to foster right ideas about engineering education by requiring of candidates for admission to its membership that they should not only give evidence of practical experience, but should either pass an examination in theory or hold an exempting University degree or certificate. In some respects these regulations are unduly inelastic; on the other hand, they do not prescribe that the candidate should have had a properly organised course of scientific study. To pass an examination in certain sciences is one thing: to have had the advantage of a University or college course in which the same sciences are well taught is quite another thing. It would probably be harsh on some deserving candidates if the college course were made a *sine qua non*; but one may hope that as time goes on the candidates who have not graduated after a full course of engineering theory will become few.

One may note in passing that the sudden growth of industrial electricity, in its application to lighting and to the distribution of power, which took place about 30 years ago, gave an immense impetus to engineering education. It became obvious then that rule-of-thumb methods would not serve an engineer confronted with such novel material, so a knowledge of science became a recognised essential in his equipment, and engineering schools sprang up everywhere. As might be expected, the result of this movement has profoundly affected British engineering. It came at a critical time, when the stress of foreign competition was beginning to be felt, and we were at a disadvantage from the fact that the foreigner saw the need for scientific training sooner than we, for the most part, saw it. Even now it may be questioned whether our eyes are as open to it as are his; I do not think they are. But even as things stand, much has been accomplished. You have only to refer to the Papers that are read before our engineering societies or listen to the discussions that take place in them to be aware that a new generation of engineers has arisen whose mental outlook is different, who are familiar with the concepts and language of science, who think and speak in terms that would be unintelligible to men of the old school. And in listening to them you find that the new phrases and the new ideas are not the expression of a culture lying outside of their professional life. Science has become part of the very fabric, it helps to determine everything that the engineer does.

A striking feature of the engineering schools is their general likeness—the substantial uniformity in method which has now been evolved. This tendency is, in part, due to the similarity or identity of text-books, and also in considerable part to the very useful practice of having the professor in one institution serve as external examiner in another, in association with the professor there as internal examiner. This practice is now generally followed, and it is in every respect a sound way to conduct examinations to have collaboration between the teacher whose pupils are to be examined and some independent person possessing expert knowledge.

The most conspicuous difference, as regards organisation, is that in some schools the division of engineering into branches is carried farther than in others; specialisation begins earlier and is more pronounced. Premature specialisation means narrowness, and it is the business of the University to save the young man from that by laying foundations that are broad and deep, on which the superstructure of professional knowledge will afterwards be built. In those British Universities which first took up the teaching of engineering the ideal aimed at was to lay a general foundation; no attempt was made to give detailed information on professional subjects. From this ideal there has been in some instances a considerable departure; the American and Continental methods, in which professional detail occupies a large place, are now more closely approached in several British schools.

The differentiation of professorships tends towards this. It allows of and practically compels a more thorough treatment of each branch, but it has serious drawbacks. There is apt to be a lack of co-ordination and balance between the various parts of the engineering school, and the student who wishes a general course is not well provided for.

What, then, are the fundamental subjects which primarily require attention in the education of the engineer? First, there is mathematics of the practical sort, to be regarded as a tool and not as an end in itself. Then there is mechanics, or, as we may better describe it, applied mechanics, of all the engineer's studies surely the most important. After this, mechanism, the strength of materials and the theory of structures, prime movers and applied electricity. Mechanical drawing is also an indispensable part of his equipment because it is the very alphabet of expression on the part of the engineer. Closely connected with drawing is the art of surveying in which the student has to learn certain conventions of representa

* Abstract of a Paper read at the Imperial Education Conference last week.

Digitized by Google

both as well as modes of measuring distances and angles and levels on the ground. Finally, there is the experimental work of the engineering laboratory; and I am a profound believer in the value of the laboratory, not only as a means of research, but as an instrument of education. Care must be taken, however, not to pay too much attention to an elaborate equipment. All teachers do not realise how much of the best laboratory work is done with the simplest apparatus; how vastly more educative it is to the student to have to rig up appliances for himself than to find everything ready to his hand. The temptation of the engineering professor is great, when funds are available, to go one better than his neighbours in other schools in the number and scale and ingeniously varied capabilities of his engines and testing machines, and so forth; but it is a temptation to be resisted. What he ought to do, however, by all means in his power, is to encourage his better senior students to undertake original research; and I am afraid this is not recognised as it should be.

The opinion used to be very general among British professors that the use of tools could not be taught in a college workshop in such a way as to have solid professional value. Experience, however, has led many to the contrary view. Personally, I have no doubt at all of the effectiveness of the college workshop as a means of professional training, provided it is set up on a fairly large scale and well provided with good machinery, and that the teaching is properly combined with skilled workmen who are at the same time competent instructors. This is borne out by our experience in the training of naval cadets.

The ordinary student of engineering must, however, look to getting his workshop experience either before or after his collegiate education. There is much to be said in favour of both plans. On the whole, the advantages incline to having the practical training follow rather than precede the other, mainly because the mental development given by the college course will make each stage of the practical training enormously more full of meaning than it can be when the pupil attacks it without preliminary knowledge of the reason of what he has to do, or sees done. Finally, the vitality of an engineering school depends largely on the professor's keeping himself in touch with engineering practice, and to this end it is very desirable that he should himself engage to a certain extent in professional engineering work. He should be not only permitted but encouraged to do so. To bar an engineering professor from outside work is to make him less efficient as a teacher, and is the way to prevent the best men from seeking or holding professorial appointments. The professor should have a free hand, subject only to an understanding that the governing body may step in if necessary to exercise a veto in cases where they find that he is abusing his freedom by undertaking work which, through its excessive amount or unsuitable character, is interfering with his duties or lowering his influence as professor.

IMPROVEMENTS IN THE TRANSPORT AND DISTRIBUTION OF GOODS IN LONDON.*

BY A. W. GATTIE.

In an address to the London Chamber of Commerce last June (*see* THE ELECTRICIAN, Vol. LXV., p. 459), I promulgated the adoption of the principle of the bankers' clearing house to the business of transport. I showed how great a benefit the clearing house had been to the banker, and I believe I succeeded in proving, by analogy, that there would be as great, or even a greater, benefit in the matter of transport.

For the present moment I only wish to invite your attention to the great economy to the railway companies which would be effected by the adoption of this bankers' clearing house system, because it would be a place where railway companies can exchange loads with one another without any shunting or marshalling, and consequently would do away with the necessity of the enormous shunting yards which they now possess. But this is not merely a question of railway economy; it is also a question, and an equally important and pressing question, of the congestion of van traffic in London streets. All traffic between goods stations would necessarily disappear, as the business could be done at the clearing house; but, more than that, it is quite clear that both in taking goods to consignees and carrying them from consignors, one vehicle instead of two would be necessary where a great number are now used. The proposed clearing house, however, would not confine itself to the mere exchange of heavy loads. It would also be equipped for the rapid handling of goods, and making up of loads, and this work could be carried out at a speed of something like 2,000 bales a minute. In the interval that has elapsed since the delivery of my speech at the London Chamber of Commerce I have been asked many questions, and one very persistently. How is it, it has been asked, if so great a benefit can be conferred on railway companies by your proposed reforms, that railway managers do not receive you with open arms? The directors of my company have been quite as puzzled on this subject as our questioners, and in order to clear the matter up and enable me to give you some definite information on the point, we last month addressed the following letter to all the General Managers and Goods Managers of the railway companies running into London:—

The General Managers of two railway companies coming into London have expressed the opinion that the project put forward by this company of establishing a central goods clearing house in London is "impracticable."

The directors of this company naturally attach considerable importance to this expression of opinion, and are therefore anxious to learn whether you endorse it?

If that is the case, may we inquire whether you claim that the alleged impracticability consists in any of the following details:—

1. The proposed electrical arrangements.
2. The proposed mechanical arrangements.
3. The proposed structural arrangements, and if so, whether in the matter of the proposed approaches or in the structure and design of the building itself.
4. The proposed system of sorting parcels, bales or heavy loads of goods by automatic conveyors.
5. The proposed clerical arrangements.
6. The proposed arrangements for elimination of shunting and marshalling.
7. The proposed arrangements for the manipulation of traffic.
8. The proposed financial arrangements, and if so, in what specific direction?

Failing the discovery of any impracticability in the foregoing features, would you so far indulge us to let us know in what shape, form or function you discover the alleged impracticability?

We should be very much indebted to you if you can see your way to do this, as we feel that the opinion expressed by the two general managers referred to must be due to a misconception or want of detailed information as to the proposals actually put forward by this company.

We shall have much pleasure in answering any question you care to put to us, or in clearing up any point of objection if made in a specific form.

Under separate cover we are sending you a copy of our Chairman's address to the London Chamber of Commerce last June.

The subject will be further discussed on the 3rd May next at the Royal Society of Arts, and any railway gentleman will be, we know, heartily welcomed by that Society.

I have received a variety of replies from the railway companies, but not one will give any endorsement to the opinion of the two General Managers, who without the remotest knowledge of any of the apparatus it is proposed to employ, expressed the opinion that the project was "impracticable." One of these general managers specifically asked how fish traffic would be dealt with under this scheme, the author therefore went into this question in detail, and showed that all the fish arriving in London would first be taken to the clearing house wharf and then unloaded into specially designed barges and taken to Billingsgate, where the usual distribution would be made.

In considering the attitude of railway managers towards the clearing house scheme, two important factors must not be lost sight of. The one is the immense force of habit of mind, and the other is the great progress which has been made in recent years in scientific apparatus. Railway managers are not scientists. The manager has been accustomed all his life to receive a goods train in London in the small hours of the morning, to have it unloaded clumsily, slowly and arduously by hand and hand truck, and having so unloaded it to allow empty trains to cumber some 50 miles of sidings for about 16 or 17 hours, when some of these trucks are again loaded and despatched from London. We are all of us creatures of habit, more so than we realise, and the railway manager is no exception to the rule. Consequently, he wants to know where we are going to store some 12,500 waggons for 17 hours in the Clearing House. So to store waggons in the Clearing House is utterly absurd and impossible, and it has never been suggested, and it is by no means necessary. The necessity only exists in the mind of the railway manager.

The second part of the Paper dealt in detail with Mr. Gattie's proposals. These have already been dealt with in the issue of THE ELECTRICIAN mentioned above.

DISCUSSION.

Mr. JAMES SWINBURNE, who occupied the chair, said one must realise that the traffic in London was largely blocked by waggons waiting and in many cases empty. In the railway yards, also, one could see the difficulty the railway companies had in loading, shunting and sorting. Their cranes seemed to be always worked endways, which appeared to be a bad system. The author had said we were all creatures of habit. He might almost say we were all savages, for everybody really opposed every-

Digitized by Google

thing new except his own new things. Mr. Gattie was tackling the big end of the problem. He had only shown us London, and nothing, practically, about the docks, but the system was also intended to deal with the docks and with other large towns. We were faced with the difficulty that new streets had to be made, but if Mr. Gattie was *right*, that could all be saved for a good many years and it would mean enough money saved probably to carry out the clearing house scheme.

Mr. C. U. FISHER (L.C.C.) said the goods vans blocked the facilities we required for passenger locomotion and for the quick conveyance of parcels. Many influential members of the London Chamber of Commerce and many members of the L.C.C. were in favour of Mr. Gattie's scheme.

Mr. L. R. S. TOMALIN said no one had attempted to amend Mr. Gattie's figures, and if his scheme had been a wild one some statistics would have been presented to show this. The congestion of our streets was worse than ever. He, himself, endorsed the scheme, and thought that its being brought before the Royal Society of Arts would lead to its receiving increased support.

Mr. S. CHAPMAN said he fully appreciated the value of electricity for working the machinery for this scheme, but, although 200 cranes might promptly unload the trucks, he doubted whether there would be sufficient goods to fill the trucks again, and there might, consequently, be a large number of empty trucks to be conveyed to a point where they could stand until they were again required. With regard to the clerical labour, he thought this would be so considerable as to modify Mr. Gattie's figures.

Mr. H. MURRAY asked if Mr. Gattie could show that any considerable profit could be made on the basis of current rates.

Mr. W. L. MADGEN thought that, with the assistance of electricity, some scheme of the kind would sooner or later be adopted. He was doubtful, however, whether Mr. Gattie's scheme would alleviate the congestion in the streets. He thought the only solution of that question was in an organised redistribution of industries.

Mr. S. WATERS said most of the opposition came from the railway companies, which was not surprising, seeing that Mr. Gattie proposed to take away a large portion of their terminal revenue.

Mr. GUY LIDDELL said Mr. Gattie's scheme showed how an enormous improvement could be made in regard to goods traffic, and he thought a good case had been made out. It was difficult to imagine anything more unsystematic than the present arrangements, which were unprofitable, both to the public and to railway shareholders.

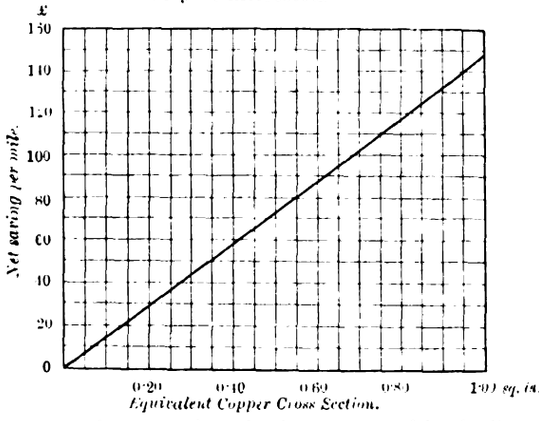
Mr. A. G. SEAMAN said the principal cost of transporting goods was not the cost of hauling but that of handling at the terminals, and people would appreciate Mr. Gattie's scheme more fully when they appreciated that fact.

Mr. GATTIE, in reply, said his calculation as to the six months' laden mobility and 17 years' life of railway wagons included the whole of the goods and mineral trucks. It showed 3 per cent. efficiency. The efficiency for the general merchandise trucks was nearly the same. With regard to the question of centralisation or decentralisation, there would be 2,000 wagons on the streets instead of between 30,000 and 40,000, and he thought enormous space economy would be arrived at by doing away with 80 or 90 per cent. of these vehicles. His 2,000 cars would make about four journeys a day, but it was the vehicles standing still that caused the congestion. They must reduce the question to van-space minutes; a car which went two miles an hour would occupy the streets twice as long and twice as much as one that went four miles an hour. With regard to the terminal charges, if the New Transport Co. could do for 3d. what the railway companies did for 1s., the railway companies and the public could both have a share of the money saved and nobody would be injured. He was substituting for the hand truck an electrical apparatus which would, he believed, do the work of 80 men, but there was no alteration involved in "documentation." The electric conveyor was absolutely honest, so that the bookkeeping need not be quite so strict as in the present system. They could handle girders or anything else in the clearing house better than it could be done in the existing goods stations. With regard to a man who used his own cart to take goods to a station which was almost next door to him, one of the New Transport Co.'s cars would call and he would not want his own cart. There would be storage accommodation in the clearing house. The cubic contents of the clearing house were 117 million cubic feet, without including the crypt. The question of profit had been gone into by chartered accountants and other people capable of dealing with the matter, and they found that, taking current rates on a revenue of £10,000,000, they would save something like £6,000,000 a year. That was a 60 per cent. proposition.

Austrian Electricity Works.—The Electrotechnische Verein will publish in July next in a collected form statistics of all the electricity supply works in Austria and Bosnia-Herzegovina (numbering about 800), and also the distributing stations taking bulk supplies serving 1,600 districts. The book is entitled "Statistik der Elektrizitätswerke in Osterreichs." Owners, populations, date of commencement of supply, systems of generation and distribution and voltage, capacity of generating plant and accumulators, numbers of incandescent and arc lamps connected, electricity meters in use and motors connected, with their capacity, prices of energy, methods of charging, capital outlay, annual output, places and works to which power is supplied, &c. The Verein announce that the work is not published for profit but with a view to serving a public need and especially the interests of the electrical industries.

INSULATED ALUMINIUM CABLES.

Although aluminium is now being used extensively for overhead conductors, it has so far been little employed for underground mains, partly on account of the increased size of cable necessary (which is, however, to some extent offset by the reduction in weight), and also due to the difficulty of making satisfactory joints on such cables. With improved methods of manufacture and the consequent reduction in price of the metal, however, the question as to the desirability of using aluminium insulated cables has become of considerable importance. We have received from the British Aluminium Co. a copy of a Table giving the aluminium equivalents of standard sizes of paper-insulated and lead-covered copper cables. This Table has been prepared in accordance with the specifications of the Engineering Standards Committee, and gives, in addition to the equivalent size of aluminium cable, the number and diameter of wires, thickness of dielectric, thickness of lead sheath, overall dimensions, weight per mile, &c. The Company will be pleased to send copies of this Table to any of our readers who may be interested.



The accompanying curve has also been prepared by the Company to illustrate the saving which can be effected by the use of lead covered paper-insulated aluminium cables, as compared with copper cables of equal carrying capacity. The saving is based on a cost of raw copper of £60 per ton and of aluminium wire at £93. 6s. 8d. per ton.

ELECTRICAL TRADES BENEVOLENT INSTITUTION.

The following is a list of the donations and subscriptions received by this Institution on the occasion of the Festival Dinner on the 26th ult. We may mention that the list is still "open" for further contributions.

LEGAL INTELLIGENCE.

British Westinghouse Electric & Mfg. Co. v. Electrical Co.

On Thursday last week Mr. Justice Swinfen Eady commenced the hearing of this action, which related to the alleged infringement of the Serrin arc lamp patent, No. 18,786 of 1902.

Mr. Walter, K.C., Mr. J. Hunter Gray and Mr. E. Russell Clarke were counsel for plaintiffs; and Mr. Bousfield, K.C., and Mr. Colefax were for defendants.

Mr. Walter said the patent had already been before the Courts, and its validity had been certified in the Court of Appeal. The patent related to an arc lamp of a kind suitable for burning what were known as flame arc lamps. In such lamps were fixed two carbon pencils in contact, which mechanism were withdrawn from each other with the result that the current passed from the point of one carbon pole across a gaseous space to the point of the other carbon pole, with the result that what was known as the arc light was obtained. There were various means by which the carbons in arc lamps were separated. Most of the arc lamps were on the principle of vertical carbons which were brought into contact and then separated until a suitable arc was obtained. There had also been certain suggestions for lamps in which the carbons were placed at an angle to one another, the points of which approached each other and were then separated to form the arc; but none of these ever came to anything. There were other devices, too, in the early days of electric arc lighting, but eventually a time arrived when the flame arc carbons came into use. These differed from the ordinary carbons inasmuch as they contained a percentage of salts (fluorine or chlorine), mixed with the carbons, which had a result of forming a better contact, producing a longer arc, and also varying the colour of the flame. Instead of the old white, non-permeating light, a coloured flame was produced of far greater permeating and decorative value. Despite this, however, these carbons had their own difficulties. It was very difficult to get them of such a fine quality that it was possible to depend upon the existence of the arc remaining constant for any length of time. There were variations in the resistance of the arc which rendered it impossible to keep the current regular. Also in the longer arc any draughts to which the flame was exposed had its effect upon the flame, and interfered with the existence of the arc. A means of delicate adjustment was, therefore, required. Bremer, in his invention, went back to the suggested, though not commercially applied, form of arc lamp in which the carbons were vertical but were inclined to one another, so that the carbons were in fact meeting at their lower ends. This position of the carbons had the advantage over the vertical carbons, because the light was unobstructed in its passage from the lamp to the ground. There had been various suggestions for fixing carbons in such a position, but the problem was not satisfactorily solved until Bremer brought out his invention for flame arc lamps. First of all he selected the type of lamp to be used—that with the electrodes pointing downwards—and the next point laid down was that all downward pointing electrodes were useless for the required purposes in all cases in which the carbons depended for the feed of the current into them on any frictional device—viz., a current passing from a spring or by rubbing against a ring, the pressure of which was alternatively on and off. Having laid that down, Bremer said he must have carbons into which the current was fed by a rigid connection—that was to say, by a wire clipped to the carbons. The next thing he said was he must have a device by which both carbons moved together and equally for the same distance, and a further device by which the carbons should be capable of horizontal adjustment. Having made up his mind to the necessity of these things Bremer eventually produced a device on the market which successfully solved the problem of flame arc lamps. The invention, which was the one plaintiffs alleged defendants had infringed, related to the class of arc lamps in which the electrodes were inclined to each other, and both pointed in a downward direction, the arc being formed at their lower extremities. The object of the invention was to provide an improved means for causing the ends of the electrodes to approach and touch each other and then for the purpose of striking an arc, such means being also applicable to maintain approach of the electrodes when the arc, by reason of the consumption of the electrodes, became lower than its normal length. In lamps of this kind the points of the electrodes usually projected through orifices in a plate at the top of the globe, or what might be called the bottom plate of the lamp, as it formed the bottom of the case containing the mechanism which controlled the carbons causing them to feed simultaneously and through the same distance so as to cause the electrodes to approach each other when the lamp was burning. In the downward feed mechanism he provided a device whereby the points of the electrodes to directly approach each other by giving both of the electrodes a swinging movement. His invention was in lamps of the type in which the current was supplied to the carbons by flexible trode holders, in which the upper ends of the electrodes were rigidly clipped, and which were capable of being lowered simultaneously through the same distance and about one of which the lower electrode could swing under the action of a device acting on the lower end. That (continued counsel) was the type of lamp which defendants had infringed in practically every particular, for their lamp, with the exception of certain additions, was identical with the Serrin lamp. Counsel described defendants' lamp in order to show the jury and produced a model. He also read the judgment given on appeal in the other action in which the validity of plaintiffs' patent was upheld.

Defendants denied any infringement, and declared that the original claims of the letters patent were not framed in good faith or with reasonable skill and knowledge. Further, they alleged prior user.

Mr. James Swinburne said he was familiar with what had been done in the early days of arc lamps. The first carbons used in arc lamps were not very satisfactory. Leaving out a very early form of lamp, all commercial arc lamps were fitted with vertical carbons. In the early eighties there were lamps in existence with two horizontal carbons, but they were not numerous. As time went on the carbons used in arc lamps were much improved, and a sudden change in their development took place when the impregnated carbons came into use. Various salts were used in the manufacture of the carbons which affected the resistance of the arc, and especially the colour of the light. When they were introduced they caused considerable trouble owing to the irregularity of their burning. In fact, prior to the introduction of the Bremer patent no successful flame arc lamp had been placed on the market. That invention applied to oblique carbon lamps, and the special point about them was that they had got a downward feed mechanism, whilst, unlike the old form of carbon lamp, the carbon always moved in one direction. The end of one of the carbons moved in a horizontal direction, and the two movements were so connected that an excessive horizontal movement resulted in subsequent vertical movement, and there was no pull back on the carbon. He had examined defendants' lamp, and the differences between it and plaintiffs' lamp were in the nature merely of additions, and were not alterations to the Bremer principle.

Cross-examined by Mr. Bousfield: The impregnated carbons were somewhat irregular in the way they burnt, especially in the early days. The beginning of flame arc lighting might be placed in the early part of the last decade. He did not remember any flame arc lamp carbons that were used commercially before the Bremer patent; they were looked upon as curiosities at first, but as they were improved they began to get a hold. Long before Bremer there were hundreds of arc lamps invented. The irregular burning of carbons was a common problem in the early days. It was common knowledge that the tractile strike action was the way to deal with the subject. The cure which Bremer put in his patent was the old cure known as the tractile strike, which had been applied in the early days of electric lighting. He denied that before the Bremer specification there were half a dozen oblique carbon arc lamps in existence. There might have been another such device in existence, but he had no recollection of it. There might have been inclined carbon lamps before plaintiffs' specification, but he had not heard of them. Those who experimented prior to the Bremer specification with the oblique carbons found a difficulty in keeping the arc in a straight position. He did not know that long before 1900, in Germany, France and Austria, the inclined carbon lamp was a commercial lamp. He remembered, but did not know whether it was ever made, a lamp with arc-shaped carbons turning about a centre. That was an American lamp, but he did not know whether it was ever made. He did not remember an inclined carbon lamp in Leicester-square. He thought there must have been a difficulty in making an inclined carbon lamp, otherwise he could not make out why they did not come in before. Given an inclined carbon lamp in which the carbons were fed down in the shape of a V, there would be a little more difficulty in applying a retractile strike to such a lamp than in a straight lamp, but not much. The retractile strike was apt to describe plaintiffs' arrangement as well as that of Serrin's lamp. Witness was examined at some length as to the method of striking the arc in both types of lamps, and said that if anyone were inclined to apply what he called the retractile principle to a lamp with inclined carbons and horizontal strike he might vary the details of it indefinitely, but he might vary the method. He might strike axially, instead of making the carbons horizontal, and he might have his retractile movement axial also; or, again, he might strike horizontally and have his retractile movement axial. Another way would be to strike axially and have his retractile movement horizontal. The only thing that was limited was that he must strike axially. The retractility was not necessarily combined with the striking. He agreed that if he desired to make an inclined carbon lamp with a horizontal strike retractile, one way to do it would be to utilise the horizontal strike. They might also make the retractile movement axial. It was quite common in lamps, especially the earlier ones, for one mechanism to strike the arc which practically moved the carbons $\frac{3}{8}$ in. to $\frac{1}{2}$ in., and stayed there, and the whole regulating of the feeding mechanism was done on the other carbon. In such a case the retractile movement was done by moving one carbon and striking by the other. From that one got the improved lamps with the striking movement which does both, and that is by the top carbon only generally. If they had vertical carbons the top carbon would feed, and the bottom carbon had got an electromagnet attached to it, so that when the carbon was touched it struck and held it.

Mr. Bousfield produced a copy of "The Electrician" for October, 1880, with the view, he said, of showing that the inclined carbon lamp (not plaintiffs') was, in fact, in use long before. Witness having admitted that the Jamin lamp was one with inclined carbons, counsel read the following extract from "The Electrician": "We hear that the new premises of Mr. Samuel Brogden, on Ludgate-hill, have been lighted with Jamin lamps." And in another issue of "The Electrician" of the same month there appeared a notice that the Royal Panorama, Leicester-square, London, was lighted with 30 similar lamps.

Witness replied that he only began electric work in 1881, and unless these notices happened to catch his eye he would not know about them. In the last few years a great deal of ingenuity had been devoted towards getting a retractile effect with a horizontal strike. Defendants' arrangement tended to a more gradual and better feed. The device tended to more sensitiveness, and if one had a dash-pot that made a very good arrangement. In regard to the arrangements for pivoting the electrode

Digitized by Google

holder, he agreed that it was wrong in principle to so pivot the electrode holder that in burning up the carbon the range of movement of the lip of the carbon was doubled, while the range of movement of the armature was the same; but, while wrong in principle, it was not a fault which would prevent the lamp working. He had heard that for some two or three years the original Westinghouse lamps did not work successfully. In the commercial Westinghouse lamp of to-day he did not know whether the carbon pivoted about the electrode holder. In defendants' lamp the whole frame was pivoted, so that the pivot remained in a constant position.

COUNSEL referred to the specification of Hedges' lamp, which, he said was a lamp with carbons inclined downwards and pivotted, the arc being struck by electric magnets, and so on.

WITNESS said it was merely a paper document and would never work efficiently in practice. He had not tried it, but he knew it would not work because the carbons were held by two other electromagnets and one was always released before the other. The result was that after burning a little while one would release and the carbon would pass under the nose of the other and drop out because there was nothing to stop it.

Mr. EDWARD MARSHALL, commercial manager of the Union Electric Co., said his Company were agents for Messrs. Körting & Mathiesen, manufacturers of the "Excello" lamp. Witness's firm paid the patentees a royalty on the sale of the lamp and up to the present time had disposed of about 19,500 of them in this country. A considerable number had also been sold under the foreign patents. The lamps were made in Germany and his firm were the selling agents. His firm did not take any lamps from the British Westinghouse Company, nor had they done so during about eight years in his recollection. He could not say whether the type had remained identical throughout that period. Messrs. Körting & Mathiesen were the sole makers of this lamp and he agreed that the British Westinghouse Company made a lamp on very similar lines.

This concluded plaintiffs' case.

Mr. BOUSFIELD, K.C., in opening for the defence, said that according to his learned friend they were dealing with a specification which had to do with arc lamps the merits of which depended on its utility for flame arc lamps, whereas on the face of Bremer's specification he submitted it had no more to do with flame arc lamps than with any other lamps which had been used for the past 30 years. Electric arc lamps with downwardly-inclined carbons one of which was pivotted for the purpose of striking horizontally, were a perfectly well-known type of lamp at the date of Bremer's specification. It had been clearly demonstrated and admitted that the difficulty which arose from the irregularity of the burning of carbons was one of the earliest defects in the early days of electric lighting. That defect had been remedied. It was also admitted that the defect introduced by the impregnated carbons was precisely the same difficulty which had existed in the older form of carbon and the method of solving it was precisely the same. The one thing it was desirous to obtain was the retractile action, but Bremer's specification did not say a word about that. All Bremer dealt with was the action of gradually approximating carbons one to another as they burnt away. It was doubtful whether Bremer ever had in his mind any idea of dealing with the problem of retractile movement. None the less it was an old problem and had been thoroughly dealt with on every scientific principle. The majority of lamps had been made with the retractile action before Bremer's specification, and unless it was present it was impossible to burn anything but first-class carbons. That being so, there was no difficulty about anyone choosing to apply the principle to a type of lamp with downwardly- pointing electrodes one of which was pivotted. And it was on the ground that Bremer applied the old retractile strike principle to inclined carbon lamps (which was also an old unsolved problem) that plaintiffs now claimed an injunction against defendants' lamp. Bremer in his specification had declared: "My invention lies in the introducing of the idea. There are many types of old lamps which will provide the mechanism, &c., by which my idea might be carried out." Surely his Lordship would not hold that such a contention formed suitable subject-matter for patent rights. As a matter of fact it was in devising a mechanism for the successful application of the principle where the real ingenuity came in. Counsel pointed out that the mechanism for the simultaneous lowering of the carbons, which was the essence of the practical working of the lamp, was so shown in Bremer's specification as to be absolutely useless. He denied that defendants had been guilty of any infringement because, he submitted, that if defendants' lamp differed by so much as one factor from that of the plaintiffs' it was sufficient to avoid infringement. Counsel then dealt at great length with the minute details of the two lamps in question. Defendants' lamp (he said) was a far better lamp than that described in plaintiffs' specification and yet plaintiffs were declaring that if defendants wanted to burn impregnated carbons in their lamps they were not entitled to use a principle which was common knowledge and apply the well-known principle of the retractile strike. In Fig. 1 of plaintiffs' specification they had the very worst arrangement, namely, an armature which went flat down on the face of the magnet. His Lordship was not told that, in order to get the necessary equilibrium, not only in the two positions which every lamp must necessarily have, but also in the intermediate position, which was necessary for floating in order to get a proper adjustment of the spring and the magnet, a great deal of knowledge was required and a good deal of difficulty might be experienced. There was not a trace of how to do that in plaintiffs' specification. Bremer had said that the idea of making it retractile was where his ingenuity came in; it was just to think of it and then the ingenuity of any ordinary workman would be quite sufficient to work it out. He only drew attention to that in order to again emphasise that an invention must have utility. In plaintiffs' specification no useful combination was described. Not only did they have to add from common knowledge to make a complete specification, but they also had to alter what was not there. What became of the utility of a combination which had elements like that? In plaintiffs' lamp the inventor had chosen to limit himself to the electrodes firmly clipped, to simultaneous lowering through the same distance, and to an electrode holder which was pivotted so as to swing under the action of a device acting near the lower end, and he could not, therefore, be permitted to say that those were not essential things. His submission, therefore, was that one of those features being different in defendants' lamp that was sufficient to relieve them from the charge of infringement. Referring to Graham's American specification, counsel said that if a person were to take it with the common knowledge which they all agreed one would have to use in working out a specification, he could not fail to make a lamp which was indistinguishable from plaintiffs'. What a curious position it would be if that were not enough to destroy the validity of a patent. Plaintiffs declared that their invention really consisted of applying a retractile strike to inclined carbons, and they said they had with great ingenuity come to the conclusion that the real way to do that and solve the problem was to have a horizontal strike and make that strike retractile. That was the way in which they were approaching the matter and they were entirely giving the go-by to the fact that the lamp with a horizontal strike and inclined carbons was an old lamp. They had not invented that type of lamp. All they had done was to say: "We want an inclined carbon lamp and we will take the old lamp with horizontal strike and make it retractile." Put in that way it was not an invention. The only way plaintiffs could make it an invention was by saying: "There were various alternatives before us and it would have been quite easy for any one to go wrong when he conceived the idea of utilising the retractile strike in inclined carbon lamps. We have saved him the trouble of going wrong and have pointed out how he can go right by means of a horizontal strike, and so on. He (Counsel) submitted, however, that it would not have been so easy to go wrong. Seeing that the majority of such lamps had got a horizontal strike and that it had got to be made retractile, to do so in any other way than that suggested in plaintiffs' specification would have been going out of one's way to accomplish it. In order to entitle plaintiffs to get any monopoly of the idea of applying the retractile strike or the retractile action to the horizontal strike in inclined carbons they must have invented, at all events, one practicable way of carrying out the idea. It was clear in that case that plaintiffs had not disclosed that, and the mere fact that he does it in the claim and amending phrase did not necessarily make it a good invention.

Prof. JOHN D. CORMACK said that in 1902, the date of the Bremer specification, the problem of the retractile strike in lamps with vertical carbons had been completely solved. It was not accurate to say that in 1902 lamps with downwardly-inclined carbons were unknown; there were few inclined carbon lamps. They had not come into extensive use, but they were known. Flame arc lighting was quite well known in 1902. The whole subject was worked out in 1880 with regard to the effect of different chemicals on the carbons. So far as a lamp with downwardly inclined carbons was concerned the problem of obtaining a retractile strike was the same problem as in the case of a lamp with vertical carbons. The solution in Bremer's specification was the same electrically, but mechanically it was different from that for vertical carbon lamps. The principle of solution was the same. It was quite possible to have a retractile strike without floating. Floating was not specifically mentioned in Bremer's specification, and at first reading his own idea was that it was not intended to deal with floating at all. It was quite clear that it did deal with the horizontal swing of the carbon before downward feed. If floating were required the mechanism shown in Fig. 1 of the specification was of the very worst type with the direct approach of the armature to the magnet, and in Figs. 2 and 3 the mechanism was of the floating type so far as solenoid is applied, but inasmuch as the iron checks are placed on the solenoid that diminishes the floating effect, making it more like a magnet with a direct approach. It was evident that there was no mention of a flame arc lamp throughout Bremer's specification. Reading the specification as an engineer, he saw no reason to suppose that Bremer was especially contemplating flame arc lamps. The construction was equally applicable to an ordinary lamp as to a flame arc lamp. On page 2 the mechanism described in Bremer's specification appeared to make the carbons descend simultaneously, but in practice they did not do it very well. That was due to the see-saw action owing to friction. Witness considered that plaintiffs' patent was for an arc lamp having an arrangement of a horizontal swinging movement taking place before the downward feed. That was, in fact, a broad claim for all lamps of that description. The natural way of making the strike retractile with downwardly-pointing carbons was to make it in the direction of the arc. A man setting out the problem might try and make the strike longitudinal, but the natural way was to make it horizontal. The purpose of the retractile strike in those arc lamps was the same, in the first instance to form the arc, to bring the carbons together and separate them to the required distance. The purpose of making it retractile was to overcome irregularities in the carbons. The flame arc carbons were no more irregular than the carbons which used to obtain in the early days. Bremer pivotted the electrode holder, which electrode holder was one sliding downwards as the carbons fed downwards, but in defendants' lamp that device was absent. The frame and guides moved and not the carbon holder. If one took Bremer's specification as a whole, reading it and having the drawings, he thought that it required to be altered in a great many particulars before it could have any commercial success. A commercial lamp was certainly not described in plaintiffs' specification. The use of a dash-pot was simply the application of what was common knowledge to the means to overcome pumping, and was common knowledge at the date of Bremer's specification. Graham's specification was in most respects simi

Digitized by Google

Bremer's. In Graham's lamp, which was prior to Bremer's, a floating action was obtained—indeed it would be difficult to prevent Graham's lamp floating. In regard to Crosby's specification witness described the working of a model in detail with a view of showing that the action was much the same in principle as that of plaintiffs' lamp. Wright's specification showed (he said) a very satisfactory device for floating. It was very sensitive, but the downward feed was bad. That arose from the method of adjusting the clutches. Bremer's specification in regard to the adjustment of the clutches was also bad; he had tested it and found that it was so in actual working. So far as floating in arc lamps was concerned Bremer's specification did not make any advance on the common knowledge obtaining in 1902. So far as sensitiveness or the means by which floating was obtained the method generally, as shown in Bremer's specification, was not so good as that in Graham's.

Mr. Justice SWINFEN EADY: Do you say that there is no advance by Bremer on common knowledge in any respect?—Quite so, not in any respect.

In cross-examination by Mr. WALTER, K.C., he said his evidence was consistent with the evidence he gave at the last trial in regard to that specification. He admitted that the Graham and Crosby specifications had never been put on the markets. He could not say that he remembered any other case of inclined carbons at the time of Bremer's specification in which there was any suggestion of adjustment and movement of the armature as provided in plaintiffs' patent. Reading plaintiffs' specification, he said that an electrical engineer reading it through would arrive at the conclusion that a floating action was intended. An electrical engineer with a considerable amount of ingenuity could make something from Bremer's specification of commercial value. There was nothing specifically mentioned in Graham's specification about floating, but magnets as equivalent to magnets were mentioned and that implied floating action. He agreed that it would be difficult to make a commercial lamp from Wright's specification. He did not agree that flame carbon lamps were contemplated in Bremer's specification. There was nothing there to call attention to them. An electrical engineer with considerable knowledge might endeavour to get floating because it was desirable to get a floating action. There was nothing about flame arc carbons in Bremer's specification. He had not seen any of his work until after the application. He should be surprised to hear that he was the man who suggested flame arc carbons. He certainly did not know it. He admitted it was true that defendants had got every single element in their total combination; and all they had done was, instead of moving the carbons at a certain point, they swung the rods upon which the carbons were supported.

In re-examination WITNESS said that at the date of Bremer's specification there was a known type of inclined carbon lamps, in which one carbon was pivotted so as to give a *horizontal* strike. Applying common knowledge at that day he would have no difficulty in knowing what he had to do in order to make the strike retractile.

Dr. S. P. THOMPSON, Mr. ANDREW FORBES and Mr. GEO. MILLS were subsequently called for the defence.

Counsel for the parties had addressed the Court, his Lordship reserved judgment.

Frost v. Kotyra and Another.

This action, which was brought by Mr. Tom Frost against Mr. Max Kotyra and the Count de St. Euilhem for damages for breach of contract, came before a jury at the Middlesex Sheriff's Court on Tuesday last for assessment of damages. Defendants were neither present nor represented.

Mr. Connor, for plaintiff, said Mr. Kotyra was the inventor of an automatic machine called the Kotyra transmitter and perforator, an improvement on the Wheatstone instrument in use by the Post Office and the cable companies for telegraphic purposes. The invention enabled unskilled reduce the work of telegraphic operators to a minimum. Count de St. Euilhem was associated with Mr. Kotyra, and they decided to start a company with a capital of £100,000, of which they would allot £60,000 as the purchase price. In 1904 they were introduced to Mr. Frost, and he introduced the machine to the notice of many influential people, and gave practically six years' work, counsel said, to the matter. The terms were that plaintiff was to have an interest of 10 per cent. in any syndicate or company that might be formed. At the end of six years Mr. Kotyra informed plaintiff that their plans were changed. They had found a wealthy partner and did not propose to proceed with the formation of a company, and they offered him £200 or £300 for his services. Plaintiff protested, and later the offer was increased to £500, but that was also declined. Plaintiff said the machine had been installed in the G.P.O. He had made many journeys in connection with the business and had to pay all his own out-of-pocket expenses. He had never received a penny for what he had done or received.

The jury awarded plaintiff £2,000 damages and costs.

In re Lodge's Patent.

On Friday last Mr. Justice Parker delivered his reserved judgment in the matter of Sir Oliver J. Lodge, F.R.S., and the other owners of No. 11,575 of 1897, for "Improvements in Syntonized Telegraphy or Wireless," under sec. 18 of the Patents and Designs Act, 1907, for an extension for a further term of the patent. The facts were given in THE ELECTRICIAN for April 7.

In giving judgment his Lordship said that in the system of wireless telegraphy protected by the letters patent the subject of this petition full use was made for the first time of the principle of resonance or syntony. The difficulty of utilising that principle had been fully explained by the patentee himself, in 1894, in his well-known lecture before the Royal Institution. Electric oscillations in a good radiator were rapidly damped, and did not, therefore, give rise to such a long series of waves as was required for the purpose; and, on the other hand, a receiver which was a good absorber of wave energy was for that reason unable to accumulate the effect of a series of waves. The patentee solved the problem by a compromise between the radiatory and oscillatory qualities of his transmitter on the one hand, and between the absorbing and accumulating qualities of his receiver on the other. Sir Oliver Lodge was the first to realise what was now beyond dispute, that a certain diminution in the radiatory qualities of the transmitter or the absorbing qualities of the receiver would, so far as efficiency was concerned, be more than compensated by the cumulative action of a series of ether waves, and, further, that, by rendering his receiver responsive only to a train of waves, he could tune out all sending stations which were not working with the same wave length and so secure selectivity. The patentee effected his compromise by the introduction of an induction coil between the two capacity areas of his transmitter and receiver respectively, thus not only diminishing the natural frequency of his circuits but also increasing what had been referred to as their "electric inertia," and in that way enabling the transmitting circuit to create, and the receiving circuit to accumulate, the effect of a series of waves as opposed to one or two waves of great amplitude. In the practical working of this system the coherer was removed from the path of the receiving circuit in which it would hinder the accumulation of wave energy. The patentee placed it in a derivative circuit, into which there could be an overflow of the energy accumulated in the receiving circuit. Great precision of tuning being required, the patentee provided an adjustable induction coil, or two or more induction coils, which could be switched in or out of circuit as desired, the object being not only to secure precision of tuning between the transmitter and a single receiver, but to enable the operator to adjust the transmitter to various receivers at different receiving stations. The patentee disclosed means of bridging the spark-gap of the transmitter so as to enable it, when disconnected with the charging circuit of the Ruhmkorff coil or other instrument employed, and when connected up to the coherer circuit, to be used as a receiver. The patentee conceived that the oscillations in the transmitter could be adversely affected by its metallic connection with the source of supply. Therefore he provided means of charging the transmitter by impulsive rush without any such metallic connection, and he conceived that the oscillations in the receiver might be adversely affected by its metallic connection with the coherer circuit, and he therefore linked the circuits of the receiver and coherer respectively by means of an ordinary transformer. If the claims of the specification were examined it would be found that the first and second related to the compromise and covered the introduction of inductance coils between the two capacity areas of both transmitter and receiver, enabling the one to create and the other to accumulate the effect of a series of waves. The third, fourth and fifth claims relate to the means employed by the patentee for tuning the transmitter to a single receiver or to different receivers at different receiving stations, and of enabling the same instrument to be used either as a transmitter or receiver. The sixth claim related to the means employed for charging the transmitter by impulsive rush without metallic connection with the source of supply. The seventh claim was for a combination, including two capacity areas of a particular shape, means for tuning them, a coherer circuit completed through one or both of them, and means to enable the capacity areas to be used either as a transmitter or receiver. The eighth claim was for a particular sort of coherer not now in use. The ninth claim related to the linking of the coherer circuit with the receiving circuit through a transformer to avoid metallic connection. The tenth claim was for the particular arrangements at the receiving end which were disclosed by the patentee, and the eleventh claim was for the arrangements and combinations constituting the system disclosed by the patentee as a whole.

In his Lordship's opinion it was beyond dispute that the system of wireless telegraphy disclosed by the patent was one of great merit, and, so far as concerned the utilisation of the principle of resonance and the consequent possibility of securing that selectivity indispensable for practical purposes, constituted a great advance on Marconi's 1896 patent. It was equally certain that the patentee had been inadequately remunerated. There had been various causes contributing to that result. It naturally required time and money to put the system into operation on a commercial scale. Further, at the date of the patent a really satisfactory coherer had yet to be invented, and that was only done after experiments extending over several years. Lastly, the owners of the patent had been seriously embarrassed by the Post Office monopoly, and he understood had not yet been able to obtain the licence necessary for working the system in this country. The case, therefore, was one in which the Court would naturally incline towards granting some extension of the patent, and no one had appeared to oppose such extension. The Solicitor-General, on behalf of the Crown, had, however, pointed out that all systems of wireless telegraphy at present in use involved precise tuning and that such tuning was alone rendered possible by removing the coherer from the path of the receiving circuit, and was usually effected by adjustable inductances; and further, that in most cases means are employed for enabling the same instrument to be used either as transmitter or receiver. He also pointed out that the patentee had never taken any step to prevent that being done, and he suggested that any prolongation of the patent might seriously embarrass the development of wireless tele-

Digitized by Google

graphy in this country, more especially as the patentee had no corresponding patent in other countries, with the exception of the United States of America. In his Lordship's opinion these considerations could not be disregarded, and were not entirely met by the offer of the petitioners to grant a licence to anyone who desired a licence on reasonable terms, to be settled by the Board of Trade or some expert appointed by the Board of Trade. With regard to removing the coherer from the circuit of the receiver and placing it in a derivative circuit, the patentee in his evidence laid great stress on that point, but he could not find that there was any separate claim directed to that portion of his system, although there was a separate claim for connecting the circuits of the receiver and coherer through a transformer to avoid metallic connection. He thought it probable that that omission was intentional, and was due to the patentee's experiments with syntonic Leyden jars, referred to in his provisional specification. It was true that those experiments appeared to have been operated by means of the lines of force in the magnetic field and not by ether waves. But in his lecture before the Royal Institution in 1894* the patentee showed the same experiments as illustrative of how the principle of resonance might be utilised in connection with ether waves, except for the fact that, if the circuits were opened out so as to become good radiating or absorbing circuits, there would be no train of waves on which such principle could operate at all. If, however, there was a radiating circuit which would create, and an absorbing circuit which would accumulate, the effect of a train of waves, the removal of the coherer from the path of the receiving circuit would be as necessary as it was in the case of syntonic jars. He doubted whether the adaptation of the device shown in the syntonic jars experiments to open radiating or absorbing circuits could be considered a great invention. With regard to tuning, in the sense of varying the natural frequency of a circuit, it had been long well known that this could be done by varying either the induction or the capacity, or both the capacity and the induction of the circuit. For tuning his syntonic jars the patentee had provided means for varying the induction. Under these circumstances, he could not think that tuning by means of induction coils, switched in or out as desired, or by means of adjustable induction coils, could be considered in itself a great invention. Again, he could not think that there was any great invention in bridging over the spark-gap of a transmitter so that it could be used as a receiver. The essence and merit of the patentee's invention appeared to lie in his conception of the compromise which enabled full use to be made for the first time of the principle of resonance. He had come to the conclusion that it was open to him, on the true construction of sec. 18 of the Act, to extend a patent as to one or more of its claiming clauses without extending it as to all the claiming clauses, and, under all the circumstances, he thought the justice of the case would be satisfied if he ordered the grant to the patentee of a new patent, to extend for seven years from the expiration of the existing patent, and to be confined to claims 1, 2, 6, 7, 9, 10 and 11 of the existing patent, such grant to contain a proviso or condition making it incumbent on the patentee to grant licences to all who desire to make use of the protected invention on such terms as a duly qualified arbitrator, to be nominated by the Board of Trade, shall think fit and reasonable: and he was prepared to make an order to that effect.

Re Langdon-Davies Motor Co. (Ltd.); Cree v. The Company.

On Friday Mr. Justice Neville had before him this debenture holder's action upon a motion for judgment in default of defence. It was stated that the Company in 1905 issued £5,000 debentures. The principal became payable in the event of winding up, and the company had passed extraordinary resolutions for winding up voluntarily. Plaintiff was the holder of 200 £1 debentures. There was no opposition, and his lordship made the usual debenture decree.

Wakefield v, London County Council.

This action brought by Miss F. Wakefield against the County Council for damages for injuries alleged to have been caused by the negligence of the Council's servants, came before Mr. Justice Channell and a special jury on Tuesday. Plaintiff was boarding a tramcar at Streatham, and when she had only one foot on the platform, the conductor, who was on top, gave the signal to start, with the result that she was dragged for some distance. It was alleged that although the bell was rung continuously the driver did not pull up until he reached the next stopping place. After hearing the evidence the jury awarded Miss Wakefield £1,000, and judgment was entered for this amount, with costs.

PARLIAMENTARY INTELLIGENCE.

L.C.C. TRAMWAYS AND DEVELOPMENT BILL.

A Select Committee of the House of Commons has been considering this Bill, under which authority is sought to construct a number of new tramways and to effect various street improvements.

Mr. ERSKINE POLLOCK, K.C., stated that last year the County Council owned 144½ miles of tramway on which they carried nearly 505,000,000 passengers. The proposals of the Bill with regard to reconstruction, extensions and widenings would involve an outlay of £750,000. With reference to the Cricklewood and Marble Arch line negotiations were taking place with the local authorities, and consideration of this portion of the Bill was postponed. Another of the lines mentioned in the Bill was a short one to cost £44,000, and to connect two existing tramways. It was opposed by the Brighton & South Coast Railway Co. on the ground that it would interfere with Forest Hill Station. The Committee, however, sanctioned it, subject to a point raised by the Home Office.

On Tuesday evidence was given in support of the proposed tramway (No. 11) in Lewisham to connect the existing line in Stanstead-road by way of Catford-road with the line at Rushey Green. The Committee decided to approve the line, subject to representations to be made later by the police upon the Home Office report.

Tramway No. 8, a single line in Lambeth, was withdrawn, but the Committee passed tramway No. 9, which proposes a junction with the line in Grove-lane, Camberwell, and passage along Grove-lane and Dog Kennel-hill to a junction with the existing tramway at Grove-vale.

On Wednesday the Committee approved a short junction between the County Council line and the line of the Metropolitan Electric Tramways (Ltd.) in Seven Sisters-road, thus providing a through service between the County Council system and the company's system in Middlesex. A loop line through Blackstock-road and Finsbury Park-road was also authorised.

Corporation of London Bridges Bill.—The preamble of this Bill, which authorises the construction of the proposed St. Paul's Bridge, was found proved by a Committee of the House of Commons on Tuesday, subject to certain protective clauses for interests affected. The Bill also authorises the construction of a new North to South highway to relieve the congestion of traffic in Cheapside, King William-street, &c.

Town Planning and Tramways.—An interesting report has been presented to Birmingham General Purposes Committee by the deputation which visited Germany and Austria in May and June, 1910, for studying town development.

The deputation comprised the Lord Mayor (Ald. Bowater), Councillors Harrison Barrow (chairman of Tramways Committee), Ellaway (chairman of Electric Supply Committee), Nettlefold (chairman of the Boundaries Committee), Mr. A. Baker (general manager of the tramways), Dr. J. Robertson (medical officer of health), and Mr. H. E. Stilgoe (city engineer and surveyor). The report deals with the division of towns into manufacturing and residential districts, the question of communication by road, rail and water, tramways, &c.

In regard to tramways, the members of the deputation state that from what they saw they *feel* convinced that it is unwise to run a tramway into undeveloped districts until they have been properly considered and a town-planning scheme settled, otherwise overcrowding is likely to take place. It would be a considerable advantage to the citizens of Birmingham if, when a district which is likely to develop at a reasonable rate has been town-planned, tramway communication were effected as soon as convenient, even though the tramway might be run at a small loss for a year or two. Much would, however, depend upon the character of the district and its likelihood of development. The deputation were impressed by the method adopted in Berlin and Vienna of making exclusive provision for tramways in new roads through undeveloped districts. The advantage to ordinary vehicular traffic as well as to tramway traffic, of separating those two forms of transit from each other was enormous. Much better speed could be obtained with less noise, collisions between tramcars and other vehicles obviated, and general repairs to the permanent way greatly reduced by reason of the rigid bed and paving being dispensed with. If all new main roads were made with a minimum width of 100 ft. this object could be attained. The width of carriageway required for a double line of 3 ft. 6 in.-gauge tramways, such as are laid in Birmingham and district, is 14 ft. 4 in. In some instances where the tracks were separate tracks the track was screened by trees. If trees were planted in this way on each side of the tramway, thus forming a tramway avenue, much of the objection to tramways would be removed and a charming effect produced.

In Berlin and Vienna the deputation were particularly interested in the arrangements for carrying trams over or under existing railways, and while they appreciate the difficulties presented by the narrowness of some of the main streets in the centre of the city, they feel that the Birmingham tramway system will always be more or less defective until some kind of "through" communication is afforded between one district and another. On the Continent single-deck cars with trailers are everywhere in evidence; indeed, double-deck cars are practically unknown. The system of running single-deck cars with trailers has much to recommend it. Passengers board and alight from the cars in much less time than that occupied with double-deck cars, and single-deck cars are undoubtedly less costly to work. The Board of Trade, however, have until quite recently prohibited the use of trailers in this country, but they have now permitted an experiment in London which, if successful, might induce the Board to permit trailers to be used in other places, particularly if single trailers were drawn behind single-deck cars. They are of opinion that such a system might prove of the greatest possible advantage in connection with tramways constructed in undeveloped districts.

With regard to the trackless trolley system, the uncertainty with regard to operating costs in this country, together with the high charges which must accrue for maintenance, render it impossible to make any recommendations in its favour for any of the outlying districts of Birmingham until more reliable data have been obtained. Trackless trolley cars can never deal with large masses of people like tramways can, and would, therefore, in the opinion of the deputation, be folly to install a trackless trolley system in a district which in two or three years may grow to such an extent as would render the system unequal to the traffic requirements.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aberdeen.—The Tramways Committee are considering the question of adopting the rail-less trolley system of traction and a deputation will probably visit Leeds in order to report on the experiment which is being made there.

Ashton-under-Lyne.—The Tramways Committee report a net profit of £800 on the past year's working of the tramways.

Aston.—The total income of the electricity department for the year ended March 31 was £32,880, against £30,065 in 1909.

The income includes £4,926 in respect of Erdington, against £4,572 last year. Total expenses were £18,273, against £15,483, and the gross profit £14,607, against £14,582. The net profit was £3,742 against £4,693.

Bantry (co. Cork).—The Town Commissioners have entered into an agreement with Mr. Patrick Nugent for the erection of electricity works and for public lighting.

Bath.—The Electric Light Committee have adopted a recommendation of the city electrical engineer (Mr. F. Teague) to obtain sanction to a loan of £7,500 for purchasing a 450 kw. Diesel engine and electric generator, one 300 k.v.a. motor alternator, fuel storage tank, additions to switchgear, &c.

Bermondsey (London).—The Board of Trade have intimated to the Council that, after carefully considering all the circumstances, they cannot grant the Council a provisional order for the St. Olave district.

Blackburn.—The Corporation are recommended to apply for sanction to a loan of £45,170 for extensions of the electricity undertaking.

Brighton.—The Council have approved a recommendation of the Lighting Committee to pay Mr. Arthur Wright £1,000 in discharge of all claims.

The Committee reported that on April 11, the Chairman (Coun. Campbell), Ald. Carden, Mr. John Christie and the Town Clerk met Mr. Wright and his solicitor for the discussion of the disputed question as to the amount of compensation to which Mr. Wright was entitled under the terms of his agreement with the Corporation dated Sept. 21, 1905. Under the terms of the agreement Mr. Wright was entitled to 5 per cent. per annum upon all profit earned by the undertaking in any year in excess of £5,000, subject to the proviso that in the event of an alteration in the rates charged for the supply of electricity in force at the date of the agreement the years in which such rates were in effect increased or diminished, the £5,000 should be adjusted in accordance with certain average prices in force at the date of the agreement. In 1908 the Corporation adopted a scheme by reason of which, in Mr. Wright's opinion, the provisions of the agreement respecting the adjustment of revenue were brought into operation, in Mr. Wright's opinion, he was entitled to a commission in respect of the two years four months up to the expiration of the agreement on the 29 next, amounting approximately to £2,000. After discussion, it was agreed on both sides that, in order to avoid litigation, the question should be compromised by the payment to Mr. Wright of £1,000 in full settlement of all claims on his part for commission under the agreement.

Burnley.—An inquiry was held on Tuesday into the application of the Corporation for sanction to a loan of £9,023 for extension of the mains of the electricity works and other purposes.

Coronation Illuminations.—£100 is to be spent in illuminating and decorating the *Fulham* (London) Town Hall on the occasion of the Coronation.—Some of *Hull* Corporation's electric tramcars are to be decorated and equipped with coloured electric lamps during the festivities.—*Wigan* Electricity Committee have decided to supply free illuminations on June 22 and 23 free of charge to their consumers.—In addition to the other illuminations on the sea front the Brighton Corporation are recommended to spend £100 on the illumination of the Aquarium at Coronation time.

Derby.—The Council have applied for sanction to a loan of £8,500 for extensions of mains (£5,250), services (£500), motors (£2,000), meters and switchgear (£750).

Dublin.—The adjourned L.G. Board inquiry into the application of the Corporation for permission to borrow £128,129 for extensions of the electricity undertaking was resumed on Tuesday.

The electrical engineer, Mr. Mark Ruddle, supplied particulars of the proposition of the undertaking, and also technical details of the proposed extensions.

The inquiry was adjourned.

Dundee.—On Monday the Electricity Committee decided to accept tenders for a new sub-station at Downfield.

Eccles.—An unopposed inquiry was held on Friday into the application of the Corporation for sanction to borrow £3,783 for extensions of the Cawdor-street electricity works.

Certain streets are to be lighted electrically at an estimated cost of £666.

Edinburgh.—The Electric Lighting Committee again recommend that the surplus of £7,300 on the past year's working of the electricity undertaking be applied in reducing the capital debt.

The chairman of the Electric Lighting Committee (Mr. Stevenson), in moving the adoption of the recommendation, said that in his opinion the principle of subsidising the rates from the revenue of a municipal undertaking was unfair and inequitable, and he also thought that all such surpluses should go towards strengthening the financial position of the undertaking. He reminded them that during seven years they had contributed to the rates no less than £38,867. One of his strongest objections to municipal trading for profit was that it led to municipal extravagance. That principle was dangerous from the point of view that it was fraught with dire consequences to the ratepayers if at some future time the boot was on the other foot, and they were pledged in turn to subsidise some other purpose. When all had been said, there still remained the risk of a new type of plant superseding the old, and there was always the risk of an undertaking of that kind having in a moment thousands of pounds of machinery destroyed.

Mr. RAWSON moved, as an amendment that the surplus be applied to the rates. He would like to ask either of these gentlemen what they would do if they held a great departmental business, and one of these departments did not pay and one of them was profitable? Was it not reasonable that the profits of the successful portion of the business should be devoted to the portion which was not so successful? He maintained that the revenues of the city had a perfect right to be pooled for the benefit of the whole of the ratepayers of the city. He believed they were justified in doing anything up to theft. They were entitled to do any financial juggling they liked to prevent a rise in the rates at such a time as the present.

After an animated debate the amendment was carried by 24 votes to 15.

Electrical Fitters in the Navy.—The annual report of Prof. J. A. Ewing, C.B. (director of Naval Education), states that

It has been decided to establish tentatively for a period not exceeding six years, a scholarship in the subject of electrical engineering, which will be awarded to a specially able and deserving electrical fitter apprentice who has completed his four years' course of study in a dockyard school. The scholarship is tenable at the Royal Naval College, Greenwich, for one year, or at the discretion of the Admiralty for two years. The holder of the scholarship is placed on the establishment as an electrical fitter, and in addition to his pay as such is awarded £40 a year in respect of the scholarship. After the course at Greenwich he returns to a dockyard as supernumerary electrical draughtsman, or he may serve at the Admiralty in this capacity, and after one year's service will be eligible for appointment as first class draughtsman or inspector, or second assistant electrical engineer. Only one scholarship can be held at any one time. The first award was made as from October last to the electrical fitter apprentice who obtained the highest place on the fourth year Dockyard School list in June, 1909.

Electricity in Mining.—At the meeting of the Tronph Mines (Ltd.) last week Mr. C. V. Thomas said the company were adopting the ordinary open cast method (removing the sand) which were practically valueless, and extracting the karang. For that purpose he intended to put up a small electrical plant, which would be increased as the work required.

Fire.—A fire broke out at the generating station of the Hindhead & District Electric Light Co. early on Wednesday morning, and caused an interruption in the supply of current.

Fulham (London).—Application is to be made to the County Council for sanction to borrow £9,500 for extensions of the electricity undertaking, including £5,950 for generating plant, £1,000 for house connections and £2,000 for meters.

Hull.—The Tramways Committee have decided to obtain 24 new tramcars.

The Board of Trade have approved the plans for the extension of the tramway on the Hedon-road to Market-avenue.

Hulton Pit Disaster.—The Executive Committee of the Miners' Federation of Great Britain met on Friday to consider the report of Messrs. Smilie, C. Bunfield and W. Straker on the explosion at the Hulton Colliery, Bolton.

The report is an exhaustive one and states that the character of the electrical plant and appliances were, generally speaking, in the opinion of Prof. M. W. Thornton, of a high class but the controller switch-box could not be so classed. The contacts were made and broken under oil so as to prevent any sparking; but in case of sparking were not flame proof. Had the box been of a flame-proof kind, such as could be obtained (the report continued) there was little doubt the explosion would not have happened. We do not think there was sufficient care taken to be sure that there

Digitized by Google

always was sufficient oil in the box or that the men who had to move it forward time after time as the coal face advanced had sufficient knowledge of the necessity of seeing that it was carried and placed level so as to prevent the oil from running out. The men who have to operate and examine electrical appliances such as that ought to be properly qualified electricians. We are also of opinion that in any district of a mine where gas is giving off electrically-driven machinery ought not to be permitted to be used.

Institute of Chemistry.—The pass list of the March April Examinations shows that of 13 candidates who presented themselves for the intermediate examination 9 passed, viz.,

L. E. Campbell, B.Sc., R. B. Croad, A. J. Hale, B.Sc., W. F. Hollely, W. G. Prescott, C. J. Regan, B.Sc., C. B. Roos, B.Sc., H. B. Stevens and A. F. Suggett. Of 19 candidates, who presented themselves for the final examination, 12 passed. In the branch of mineral chemistry: W. O. Andrews, A.R.C.S., C. D. V. Georgi, B.Sc., H. L. Lucking, Ph.D. and O. D. Roberts; in the branch of metallurgical chemistry: Gordon Wells, B.Sc., A.R.S.M.; in the branch of organic chemistry: E. de Barry Barnett, B.Sc., G. E. Pool and G. E. Slim; in the branch of chemistry of food and drugs and of water: S. W. Bridge, A. A. Eldridge, B.Sc., C. H. Hampshire, B.Sc. and H. M. Mason.

Leicester.—An inquiry was held on Tuesday into the application of the Council for sanction to borrow £17,000 for the electricity undertaking.

The Town Clerk (Mr. H. A. PRITCHARD) said that £12,000 was for increasing the capacity of the station to meet the demand for power and for cable extensions, &c. The remaining £5,000 was for two motor generators. The Corporation possessed two generating stations, one alternating and one direct-current. The order authorising them to supply electricity for lighting was managed by the gas department. They erected an a.c. station which had been supplying current for light. Recently, the Corporation decided it would be more economical to have the two stations under one management. They discussed the matter at length, and took the advice of Mr. James Swinburne as to what should be done. He advised the coupling up of the two stations by putting in motor generators to convert the current as occasion might require.

London Tube Railway Facilities.—The Lord Mayor on Wednesday opened the new subway between the Bank stations of the Central London and City & South London Railways.

Maidstone.—As from April 1 the charges for electrical energy for lighting in shops and other business premises will be as under:—

8s. per annum for each 32 watt lamp (or equivalent) and 1d. per unit; or as an alternative: Maximum demand system at 7d. per unit for first hour and 2d. after.

Sanction has been received to a loan of £4,099 for expenditure on mains during the next three years.

Manchester.—On Wednesday the City Council considered a report of the Tramways Committee, recommending that no further concessions be made in regard to workmen's fares.

The general manager (Mr. J. M. McElroy) has investigated the subject fully. In 1909 he estimated the cost of extending the time for the issues of workers' tickets at £20,000 per annum. On further considering the matter, and especially in view of the actual experience gained in Salford, his view is that this estimate is too low, and that it should be increased to at least £25,000 per annum. Salford Corporation some time ago extended the time during which workpeople's tickets are issued up to 8 a.m., and the concession had a disastrous effect on their revenue. As a result of the 12 months' working the income per car-mile fell from 10·44d. to 9·84d., equivalent to a difference of £14,463. 13s. 5d. and the average fare paid per passenger decreased from 1·25d. to 1·24d. Salford, after 12 months' experience, had to withdraw the concession. In previous reports Mr. McElroy pointed out that preferential treatment as regards fares tends to introduce difficulties, and he suggested that the wisest policy to adopt was to reduce the ordinary fares as low as possible—having regard to the financial stability of the undertaking—and to make everybody pay alike.

Manchester Smoke Abatement Exhibition.—A meeting was held in Manchester on Friday last of the supporters of the scheme for the organisation of a smoke abatement exhibition in Manchester in November next.

Ald. FILDES, chairman of Manchester Sanitary Committee, presided, and an explanatory statement was made by Coun. Kendall, hon. secretary of the Manchester & District Smoke Abatement Society, who are organising the exhibition. He said that the Society was formed as the result of a conversation which took place at the successful smoke abatement exhibition at Glasgow. The meeting was well attended by the patrons of the exhibition, amongst whom were the technical heads of the Manchester and Salford Corporations' gas and electricity departments, and several gas and electrical engineers from surrounding towns were also present.

Ald. FILDES spoke at some length on the injurious effects of the murky atmosphere of Manchester upon the inhabitants and said the Gas and Electrical Committees of the Corporation could help greatly by encouraging the use of gas and electricity for many purposes where at the present fuel is used.

A resolution, approving of the proposed exhibition, was carried unanimously and an Advisory Committee was appointed, consisting of the technical heads of the Manchester and Salford gas, electricity and sanitary departments, and also several professional gentlemen. Arrangements have been made with Mr. Walter Cawood, of the City Exhibition Hall, to undertake the management of the exhibition on behalf of the Society. All communications should be addressed to Mr. Cawood, 196, Deansgate, Manchester.

Marylebone (London).—The Electric Supply Committee report that for the year ending March 31, 1912, they estimate their total sales to private consumers at 11,050,000 units.

Sales during the past year show an increase of 10 per cent. over 1909-10. In estimating for the new year they are allowing for an increase of 7 per cent. only, giving a total estimated sale of 11,820,000 to private consumers. During the current year the average price will amount to 3·38d. per unit, and the committee are assuming a similar rate for the new year as to 11,050,000 units and an average of 1d. per unit only for the amount of the additional sales allowed for, thus giving an all-round average of 3·23d. per unit. As the public lighting scheme has now been practically completed the income and expenditure can be estimated closely. With regard to rents, rates and sundries the figures have been revised in view of the new assessment on the undertaking which involves an extra burden of £8,500 per annum. In addition a substantial amount had been allowed for income tax. The total liabilities for rents, rates, taxes, insurance, law, audit, expenses, &c., are estimated at £14,400, an increase of nearly £9,000, and averaging 0·260d. per unit against 0·107d. The committee point out that the sales and publicity department exists to increase the sale of current and not for earning a profit on the sale of apparatus or the carrying out of works for consumers, although it would be unfair to private traders when such works and sales are taken in hand to charge less than recognised market prices. It was estimated that the turnover for sales of apparatus, &c., during the year would amount to £16,000 and the gross profit would be such that it will meet the whole of the general business-getting and business-keeping expenses of the undertaking with the exception of a balance of £1,825. After reducing the capital debt by £40,274, a surplus of £1,018 was anticipated on the year's working.

Nelson.—During the year ended March 31, 920,456 units were sold including 303,581 for lighting, 73,008 for power, 254,900 for the tramways and 251,030 for the light railways. The equivalent of 37,000 8 c.p. lamps and 345 H.P. of motors are connected.

Obstacle to Electrical Enterprise.—On Tuesday evening Mr. G. Paish (of the "Statist" newspaper) read before the Sociological Society a Paper entitled "Savings and the Social Welfare."

In a discussion which followed Mr. CHIOZZA-MONEY said many obstacles were put in the way of the investment of individual savings in home enterprise. What, he asked, was the cause of the slow progress made in the applications of electricity in this country? He thought the answer was that the vested interests which it was feared electricity would displace were working against an advance so essential to the well-being of the community. Gas and kindred interests were in a position to put forward their claims, which were seldom ignored, and he regarded gas as an illuminant which was rapidly becoming obsolete.

Mr. PAISH disagreed on this point and said gas was cheaper in England than in any other part of the world, and, consequently, there was not really the same inducement here to establish electrical enterprise as there was in countries where fuel was expensive and electrical power could be produced very cheaply, especially from water power.

Oldham.—Messrs. Asa Lees & Co. have decided to adopt electric driving in one of their departments, and current will be taken from the Corporation mains. The firm will take about 150 H.P. at present, but ultimately they will require 250 H.P.

Pinner.—The Harrow Electric Light & Power Co. are applying for a provisional order to extend their area of supply to Pinner and other districts and Hendon Rural Council endeavoured to get the Board of Trade to insert a lower maximum price than 8d. per unit in the order. The Board of Trade have intimated that it is not usual to fix a lower price.

Poplar (London).—121, East India Dock-road is to be rented for showroom for the electricity department.

The rate for lighting premises of shopkeepers is to be reduced to £8 per kilowatt installed, and ½d. per unit for current consumed.

Provisional Orders Revocation.—The Board of Trade have revoked the Warmsley Electric Lighting Order, 1903, and the Litherland Electric Lighting Order, 1905, as from April 24.

South Shields.—An inquiry will be held into the application of the Corporation for sanction to borrow £8,960 for extensions of the plant at the electricity works.

Stepney (London).—With regard to the supply of current to consumers on time switches at 1d. per unit the borough electric engineer and manager (Mr. W. C. P. Tapper) has called the attention of his Committee to the fact that in each case a considerable expenditure is incurred in laying service in addition to an annual expenditure of £2 or £3 each to give the supply.

Mr. TAPPER states that these supplies can be given profitably between sunset and 7 p.m. during the winter months, provided the annual bill each consumer is sufficient to cover cost of current and service charges which include interest and sinking fund on the service lines and meters, cost of maintaining same, reading meters and rendering accounts. Taking a number of years this cost works out at slightly over £3 per account per annum. The initial cost of laying a service is about £8 including meters, &c. There are a large number of consumers already on this rate whose annual accounts for current vary from 11s. upwards and applications are coming in for new supplies at the same rate.

Digitized by Google

the recommendation of Mr. Tapper it has been decided that restricted supplies are only to be granted in future on condition that consumers undertake to pay a minimum half-yearly bill of £3, but accounts rendered for any other supply of electricity taken by the same consumer on the same premises shall be allowed to form part of this minimum payment.

The Board of Trade have approved the proposed new agreement with Poplar as to supply of electricity, with some small alterations.

Stoke-on-Trent.—At last week's meeting of the Council Ald. Geen made an unsuccessful attempt to get the resolution passed on the 9th March relating to the erection of a new three-phase station rescinded.

Torquay.—A scheme for the electric lighting of Princess-gardens and Pier at an estimated cost of £2,000 has been prepared by the borough electrical engineer, Mr. C. W. Salt.

Wandsworth (London.)—The Borough Council are negotiating with London County Council as to the construction of tramways from Putney Bridge to High-street, Wandsworth.

Wireless Telegraph Notes.—The "Telegraph and Telephone Age" of America states that a rough calculation recently made as to the saving of wireless telegraphic assistance at sea shows that over 3,000 lives have been saved by the help rendered through this means of intercommunication.

Steps are said to have been taken for the establishment of wireless telegraphic communication between Teheran and Bushire, thence to two other places on the Persian Gulf, and finally to Kurrachee and Bombay.

It is announced that as the results of experiments which have been conducted for some time past at Marseilles it is likely that a powerful wireless telegraph station will be established at that port.

With reference to the proposal before the Norwegian Storthing the Bill making a grant of £16,500 for the erection and equipment of two wireless telegraph stations (at Hammerfest and on Spitzbergen respectively) has been adopted.

Worcester.—The City Council have agreed to supply electricity to Messrs. Heenan & Froude.

The firm will take annually for three years, and then subject to 12 months' notice, electrical energy of the minimum value of £500 per annum.

Sanction to a loan of £10,000 has been applied for by the Council in order to carry out extensions of the plant and mains.

Worthing.—Mr. J. F. C. Snell has presented his report on the proposals to extend the plant at the electricity works.

It was proposed to install a 1,260 ampere-hour battery, two 125 kw. Diesel generator sets and one 300 kw. steam turbo-generator. In his report Mr. Snell states that the output of electricity for power appears to be increasing; the figure for public lighting has been decreasing, but has now probably reached its minimum limit. Mr. Snell estimates that by next year the number of consumers will have increased to 921, and by 1915 to 1,190. The present lighting and power units sold for the past year total 400,440, and it is estimated that for 1915 the total will be 531,100. No increase is anticipated in the public lighting units. Mr. Snell considers that the present engineer has been, and is, using skill and evident painstaking attention to detail in the economical administration of the plant under the engineering circumstances. The load factor is low, and it will probably always be low, since Worthing is mainly a residential borough. The cost of coal is high, the steam plant small, and the capital charges (amounting now to no less than £119 per kilowatt installed.) Each of these items is the engineer responsible. He considers that the department has done very well, in spite of difficulties, and that the Electric Light Committee has acted wisely in the past in forming a reserve fund in addition to the sinking fund for repayment of loans. The report details the advantages of the three alternative plant extension proposals. In summing up, Mr. Snell recommends that two 125 kw. Diesel sets be obtained at an approximate cost of £4,400, and that the present battery plates be replaced by larger plates so as to increase the capacity hours from 600 to approximately 1,000 at an approximate cost of £1,000 to be paid for out of reserve.

The Committee have approved Mr. Snell's proposals and application is to be made for sanction to a loan of £4,960 for carrying out same.

Wrexham.—The L.G. Board inquiry, announced to take place on Tuesday, has been postponed owing to representations made to the Board by Messrs. Evan Morris & Co., solicitors, who are conducting opposition on behalf of the Wrexham Gas Co. and the Wrexham and East Denbighshire Water Co.

Dinner.—The seventh annual dinner of the Faraday House Old Students' Association took place on April 26th the president (Mr. H. H. Cunynghame) in the chair. Amongst the guests present were Mr. S. Z. de Ferranti, Prof. J. D. Cormack, Mr. W. Duddell, F.R.S., Mr. J. S. Highfield and Mr. Arthur Wright.

Mr. de Ferranti, proposing the toast of "Faraday House and its Old Students," referred to the good work which had been done by the Hammersmith and its successor—Faraday House.

Mr. Rogers Hammond replied, and reminded the company that although it was only the seventh annual dinner of the Old Students' Association it was actually the 26th annual dinner of the old students.

Mr. D. Watson proposed the toast of "The Chairman," and "The Visitors" was proposed by Mr. A. F. Berry, being replied to by Mr. Duddell, F.R.S.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" reports—

The destruction of the third customs warehouse (at Buenos Ayres) by fire within three months has led the Government to place the matter in the hands of the police, and our contemporary remarks "it would have been better if this had been done when the first fire occurred, instead of letting the matter drop by coming to the conclusion that the fire must have been produced by the electric installation." The insurance companies have, however, submitted recommendations as to fire extinguishing appliances, the use of steel ducts for electric wires, &c.

The Minister of Public Works has declared as lapsed the concession granted to Quesada & Co. for a tramway from the Federal Capital to San Justo, San Martin, Moron, Merlo, Moreno, Gral. Rodriguez and Lujan.

Australasia.—The "Australian Mining Standard" states that Mr. R. P. Wilson, who is associated with Mr. C. H. Merz in regard to Mr. Merz's scheme for the electrification of the Melbourne suburban railways, recently gave evidence before the (Melbourne) Metropolitan Traffic Commission.

Mr. Wilson said Mr. Merz had prepared his report in the belief that the public and Parliament had already decided that electrification was necessary; he had, therefore, not attempted to prove the desirability of that change, but had simply devised a scheme for carrying it out. With regard to Sir Thomas Tait's criticism, there would be no difficulty in running trains with one minute headway. In the London underground system they ran trains with only 40 seconds headway. It was less dangerous under electric traction, because the block sections could be so arranged that the block intervening between one train and the immediately succeeding train could be isolated, so that if the succeeding train did enter the block, it could not proceed. Its power would be cut off. While the steam express saved four minutes, the electric express saved 11 minutes. That was the only fair basis on which a comparison could be made. No doubt, quadruplication of lines would, from some points of view, give greater benefits than electrification. But it was necessary to consider what must be paid for it, and what would be lost. The chief difference between steam and electricity was that, with electricity, for a smaller capital expenditure, you could deal with very much larger traffic at a very much reduced cost. Mr. Merz's report indicated an initial loss but an eventual profit from the proposed system. The Commissioners had said that electrification would not be justified until the increase in traffic compared with 1906 was 33 per cent. That state of affairs had actually arisen. Sir Thomas Tait expressed the opinion that the estimated cost of cleaning and repairing the electrical coaches was at least £10,000 too low, but it was an approximation, based on the actual cost of such work elsewhere, with 10 per cent. added in view of Australian conditions. He knew of nothing about alternating current that made it of more advantage than direct current. The electrical equipment and plant needed for Melbourne railways would cost for the alternating current system nearly double what it would cost for the direct current and 30 per cent. more weight would be required to give the same efficiency. He would not say that the scheme proposed by Mr. Merz would admit of indefinite, but only of considerable, expansion.

The Commonwealth Postmaster-General, Mr. Thomas, has authorised the installation at Sydney G.P.O. of the Automatic Telephone Co.'s apparatus to serve 100 subscribers, with the object of testing the system.

Kalgoorlie (W. Australia) Council have lodged a protest against the new regulations of the Fire Underwriters' Association with regard to electrical installations. Coun. Boileau, who introduced the subject to the Council, said five months after he had fitted his premises, in full compliance with the Council's regulations, he was told he would have to make alterations. In a similar way the Palace Hotel would be put to an expense of about £200. The Council's electrical engineer, Mr. D. Curle Smith, said the insurance companies had now made general rules to be accepted everywhere, but there were certain portions of them which he did not think necessary for that place. It was decided to ask the insurance companies' electrical expert to discuss the subject with the Electric Light Committee and the electrical engineer.

Mortlake (Victoria) Butter Factory Co. have adopted the scheme of F. A. McCarty & Co., Melbourne, for installing an electric lighting plant for the town at an estimated cost of £2,500. It was also decided to invite tenders for a 66 H.P. suction gas engine. Metal filament lamps are to be used and the charges will be 7d. per unit for lighting and 3d. for power. The same firm have also received instructions to provide lighting and power plant for the Nagambie Shire Council at a cost of £2,600. The charges will be the same as at Mortlake. Messrs. McCarty & Co. are also to report on the feasibility of installing an electric light and power plant for Shepparton Shire Council.

Mr. P. J. Pringle, general manager of the Electric Supply Co., of Victoria (the owners of the Bendigo electric tramways), has referred to the directors the question of extending the tramways to White Hills. Mr. Pringle has also had a conference with representatives of Sebastopol Council, with regard to a proposal that the tramways should be extended to that town from Ballarat.

The concession transferred by the Complex Ores Co. to Hydro-Electric & Metals (Ltd.) includes the right to take water from the Ouse and Shannon rivers and to conserve the water of the Great Lake, which is about the centre of Tasmania, for the generation of electrical energy. Contracts have been entered into for the street lighting of Hobart, Newton, Queenborough and Glenarchy. The estimated cost of this electricity scheme and the equipment of the metallurgical works, which the company are bound to erect, is £220,000. It is proposed to instal 5,000 H.P. plant at the outset and to increase it subsequently to 20,000 H.P. and to erect works capable of accommodating plant of 100,000 H.P. in all.

Digitized by Google

Russia.—Kharkov Municipality have applied to the Government for permission to borrow up to two million roubles (£211,112) for tramways, and 500,000 roubles (£52,778) for extension of electricity works. Tamboy Council have applied for a loan of 940,000 roubles (£99,223) for electric lighting, water supply and other works.

Turin Exhibition.—The King of Italy inaugurated this Exhibition on the 29th *ult.*

The principal British exhibitors in the electrical and engineering and scientific instrument sections include Sir W. G. Armstrong, Whitworth & Co. (Ltd.), Alley & Maclellan, Edgar Allen & Co., J. Bourne & Sons, British Ackley Brake Co., Brunner, Mond & Co., Campbell Gas Engine Co., Cambridge Scientific Instrument Co., Castner-Kellner Alkali Co., Clayton & Shuttleworth, F. Darton & Co., Crypto Electrical Co., Doulton & Co., J. J. Griffin & Sons, Holden & Brook, A. Herbert (Ltd.), R. Hornsby & Sons, Hulse & Co., Johnson, Matthey & Co., Marshall, Sons & Co., J. & H. McLaren, Merryweather & Sons, Morgan Crucible Co., Muirhead & Co., Nalder Bros. & Thompson, National Gas Engine Co., Ozonair Limited, R. W. Paul, Pulsometer Engineering Co., Reason Mfg. Co., Ruston, Proctor & Co., Simms Magneto Co., Silica Synd., W. F. Stanley & Co., Synchronome Co., E. R. & F. Turner, Underfeed Stoker Co., Thermal Synd., Venner & Co., &c.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited (up to June 14) for supply of cable, ironwork, c.i. pipes, iron or steel poles, phosphor bronze wire, &c., to the Postmaster-General's Department, QUEENSLAND; and (up to June 27) for supply of 1,400 protectors for use on main distributing frame at magneto exchanges to the Postmaster-General's Department, VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisements.

Tenders are wanted by May 19 for supply of six 60 kw. single-phase transformers, and by May 26 for 1,024,000 arc lamp carbons and for 6,000 metal filament incandescent lamps for the City of MELBOURNE electricity department. Tender forms, specification, conditions of tender, &c., from the Agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter-square Buildings, London, E.C.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z., until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, engine-room crane, circulating pumps and pipes and switchboard. Specifications and drawings at the offices of the High Commissioner for the Dominion of New Zealand, 13, Victoria-street, London, S.W.

Tenders are invited up to May 30 for the supply of one portable petrol-driven desiccating plant to the Postmaster-General's department in Victoria, and up to May 31 for the supply of 7,000 insulators and wire and line material to the Postmaster-General's department in SOUTH AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders will be received at the office of the Receiver-General and Director of Contracts, Valetta, MALTA, up to 11 a.m. of Thursday, May 11 for the supply of arc lamp carbons. British tenderers not having representatives in Malta must make a deposit of £10 in the office of the Crown Agents for the Colonies. Specification, &c., at the office of the Receiver-General and Director of Contracts, or from the Crown Agents for the Colonies, Whitehall Gardens, London, S.W.

Tenders are invited up to June 7 for the supply of 2 nauts single-core submarine cable to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS invite tenders (from manufacturers) for supply of opal lamp shades during three years, and also tenders (from manufacturers) for supply of electric gas torches during one year. Tenders by 11 a.m. on Wednesday, May 10, to the Secretary, H.M. Office of Works, &c., Storey's Gate, S.W

SOUTH SHIELDS Corporation want tenders by May 24 for supply and erection of 1,500 kw. high-pressure steam turbine (with surface condenser and pumps) coupled to 1,000 kw. d.c. generator (with switch panel, &c.) and 1,100 kw. a.c. generator (with switch panel, &c.). Specification, &c., from the Borough Electrical Engineer.

ILFORD Council require tenders by noon May 9 for the supply of distributing switchboard, feeder cable and stoneware conduits. Specifications, &c., from Mr. A. H. Shaw, Electricity Works, Ley-street, Ilford.

ST. PANCRAS (London) Borough Council invite tenders for three-phase h.t. cable and for stoneware ducts. Tenders to the town clerk Mr. C. H. F. Barrett, Town Hall, Pancras-road, N.W., by noon, May 15.

BARKING Council require tenders by 7 p.m. May 10 for extension of electricity works. Plans, &c., at the office of the Surveyor on and after May 1.

HULL Corporation require tenders by noon May 24 for extensions of Sculcoates-lane generating station and New George-street sub-station.

OLDHAM Surveyor's and Tramways Committee require tenders by May 10 for construction of about 270 yds. of tramways. Forms of tender, &c., from the Borough Surveyor.

FRANKFORT-ON-MAIN Corporation require tenders by May 20 for two 7,500 kw. steam generators with condensers.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c.; and up to June 14 for supply of a branching multiple magneto lamp signalling switchboard at Ballarat, for the Postmaster-General's Department in VICTORIA; and up to June 14 for supply of a c.b. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA. Tender forms, &c., from 72, Victoria-street London, S.W.

The Prussian State Railways Department, PADERBORN, Germany, will receive tenders until May 10 for supply of an electric lift, crane, &c.

RUSTCHUK (Bulgaria) Municipal Council require tenders by May 24 for the erection and equipment of electric light and power works. Upset price £26,000.

The Ministry of Public Works, Constantinople, will receive tenders until July 15 for the construction of electric tramways and for electricity supply in the town of ALEPPO. Specification from the Ministry of Public Works on payment of 9s. Local representation is practically indispensable.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Tubing and accessories for harnessing the water at rate of 7,000 litres a second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price 1,000,000 lir. (£40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 8 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (in Italian) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Salford Corporation have accepted the following tenders for annual supplies to the tramways department:—

W. T. Henley's Telegraph Works Co., rubber strip 8s. 6d. per lb., black tarred tape, 9d. per lb.; India Rubber, Gutta Percha & Telegraph Works Co., plain white tape 2s. per lb.; Electrical Co., d.c. meters, 100, 200 and 300 ampere sizes, schedule prices; Chamberlain & Hookham, meters, 1½ to 50 amperes sizes (part contract), value of contract £230; Ferranti Limited, meters, 1½ to 50 ampere sizes (part contract), £210, a.c. meters, £290; Brush Co., carbon filament lamps, schedule prices; L. Andrew & Co., mica sheets, 5s. per lb., short rubber gloves, 7s. per pair; North British Rubber Co., rubber overshoes, 1s. 10½d. per pair.

Salford Council have accepted the estimate of the manager of the tramways (Mr. Holford) for providing and fixing the wires, &c., in connection with the new fire alarm system at £499. 1s. 7d.

£25 per annum is to be paid to the Tramways Committee for permission to attach the wires to the tramways standards, and £15 per annum for maintaining the lines and fittings.

Salford Council have accepted the tender of B. Longfield-Beasley (at £2,131. 10s.) to furnish and install the Gamewell system of fire alarm and police telegraphs in the borough.

Poplar (London) Council received three tenders for two 250 kw. converters, with auxiliary plant and switchgear for Orchard-place sub-station:—

British Westinghouse Co. (rotary converters) (*accepted*)	£1,830
British Thomson-Houston Co. (rotary converters)	£1,839
Bruce Peebles & Co. (motor converters)	£2,110

Leyton Council have accepted the tender of Bertram Thomas at £98. 5s. for a 600 kw. traction panel and at £116. 10s. for a lighting panel.

Digitized by Google

Walthamstow Council have accepted the following tenders :—

A. Wright & Co., self-recording pressure gauge; W. T. Henley's Telegraph Works Co., annual supply of cable; W. E. Moore & Co., steam winch (£30); British Westinghouse Electric & Mfg. Co., new cylinder for gas engine, £82. 10s.

The tender of W. T. Glover & Co. has been accepted by Accrington Electricity Committee for supplying and laying an e.h.t. main to the Baxenden boundary at £4,333, and also for the annual supply of cables. The committee have let the contract for high-tension sub-station switchgear to the British Thomson-Houston Co. at £428.

Hertfordshire County Council have accepted the tender of Dick, Kerr & Co. to construct a tramway from Callow Land to the car station site in London-road, at £31,478. 9s. 3d.

Rugby Council have accepted the following tenders :—J. Young, transformer chambers and cable laying; Thos. Wragg & Sons, trenches and covers; Dussek Bitumen Co., bitumen.

Southampton Council have accepted the tender of McWhirter, Roberts & Co. for the annual supply of electric lamps to the works department.

Newport (Mon.) Electricity and Tramways Department received 22 tenders for supply of lubricating oils, and these have been referred to the electrical engineer for samples to be tested.

Worthing Town Council have accepted the tender of the Hart Accumulator Co., at £864. 11s., for replating the existing storage battery, and for maintaining same for 10 years for £715. 10s.

Torquay Corporation have placed an order with the British Thomson-Houston Co. for supply and erection of a turbo-generator, condensing plant, &c., at £4,601.

C. H. Walker & Co. (Ltd.) (of London, Rio de Janeiro and Buenos Ayres) have secured the contract for extension works at the Port of Buenos Ayres, at a total cost of about £5,500,000.

The following tenders have been accepted by Derby Corporation : British Thomson-Houston Co., inverted rotary converters; British Insulated & Helsby Cables, e.h.t. cables; Ferranti, Ltd., e.h.t. switchgear.

Stoke Corporation have placed on order with Siemens Bros. Dynamo Works for two induction motors for the Hanley works, at £285.

Heston and Isleworth Council have accepted the tender of Drake & Gorham for tantalum lamps at £7. 0s. 5d. per 100.

Bridlington Council have accepted the tender of Waring & Gillow Ltd. for lamps, &c., for electrical fountains, at £14. 15s.

Diesel Engines.—The Diesel Engine Co. states that in addition to the list of orders published in February (totalling between 3,000 and 4,000 H.P.), they have recently received a number of orders, including:—

Letchworth Garden City (repeat), one engine of 420 B.H.P.; Leek Urban, one engine of 330 B.H.P.; Reigate Council, two engines of 150 B.H.P. each; Chilian Government (per General Electric Co.), two engines of 250 B.H.P. and two engines of 200 B.H.P. each; Balfour, Williamson & Co. for Chili, one engine of 320 B.H.P.; Chichester Elec. Supply Co. (per Johnson & Phillips), (1st extension), one engine of 200 B.H.P.; G.N. Railway, one engine of 340 B.H.P.; Dick, Kerr & Co., one 525 B.H.P., one 225 B.H.P. and two 60 B.H.P. engines; Leatherhead & District Elec. Supply Co. (repeat), one engine of 60 B.H.P., and orders for about 30 other engines for London, Ireland, India, Ceylon, Brazil, &c., of about 1,950 B.H.P.

BUSINESS NOTICES.

The Newcastle-on-Tyne address of the St. Helens Cable & Rubber Co. has been removed to 8, Charlotte-square, Cross street.

Plant for Sale.—Elektron Limited (in liq.), Gothenburg, offer for sale triple expansion engines, c.c. dynamos, &c. Further particulars are given in advertisements.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of creditors of F. A. Glover & Co. (Ltd.) (in voluntary liquidation) was recently held.

Mr. W. B. Peet, one of the liquidators presented a statement of affairs, which disclosed liabilities to unsecured creditors £3,166 and a bank overdraft £317. There were also debentures for £5,888. The preferential claims amounted to £385 and the assets were returned at £10,013. Mr. Peet gave particulars of the history of the company, and pointed out that on forced realisation took place the assets might not be more than sufficient to pay the claims of the debenture holders. After discussion, a committee of five of the principal creditors was formed to confer with the debenture holders, with a view to forming a scheme in the interests of all concerned.

Wm. Hy. Illingworth (trading as the Yorkshire Metal Filament Lamp Co.), 30, Pellon-lane, Halifax, has been adjudicated bankrupt. First meeting of creditors May 10; public examination May 19 at County Court, Prescott-street, Halifax.

First meeting of creditors and contributories of the British Tungsten Lamp Co. (Ltd.), Huyton Quarry, near Liverpool, will be held on May 12 at 35, Victoria-street, Liverpool.

The Electric Fog Signal Co. (Ltd.) is being wound up voluntarily. Mr. A. T. Spear, 44, Myddleton-road, Uxbridge, is liquidator.

A first meeting of creditors of the Rhondda Tramways Construction Synd. (Ltd.) will be held at Queen Anne's-chambers, Westminster, S.W., on May 8. Claims to Messrs. S. B. Schlesinger and W. B. Cownie, at the same address by same date.

Mr. H. B. Clark, 3 and 5, Crown-court, Old Broad-street, E.C., and Mr. G. E. Corfield, Balfour House, Finsbury-pavement, E.C., London, have been appointed joint liquidators in the voluntary winding up of Arc Lamps (Ltd.). A meeting of the creditors of this company will be held at Balfour House, Finsbury-pavement, London, E.C., on Tuesday next at 12 noon.

The North Western Electricity & Power Gas Synd. (Ltd.) is being wound up voluntarily. Mr. C. E. Bullock (Messrs. Bourner, Bullock & Co.), Albion-street, Hanley, is liquidator, and will receive claims until May 30.

COMPANIES' MEETINGS AND REPORTS.

AUCKLAND ELECTRIC TRAMWAYS CO. (LTD.)—The total revenue for the six months ended June 30 was £96,959. 0s. 10d. Traffic receipts (£95,792. 13s. 8d.) showed a satisfactory increase of £6,463. 16s. 3d. over the previous six months. Deducting expenses chargeable to revenue (including £8,199. 12s. 1d. for debenture interest, the rental and percentage interest of profits payable to Auckland Council, £2,263. 1s. 5d., and £7,500 for depreciation) the surplus was £20,528. 11s. 4d., making, with £3,544. 8s. 9d. brought forward, £24,073. The directors recommend that £6,000 be placed to reserve; preference dividend (already paid) absorbed £1,500 and a dividend on the ordinary shares for the half-year at the rate of 6 per cent. requires £10,500, leaving £6,073. 0s. 1d. to be carried forward. Capital expenditure during the six months amounted to £15,233. 12s. 6d., largely in connection with the extension of the power-house plant and distributing system. An extension of 0·68 mile in the Grey Lynn district was opened for traffic on May 4, and eight further cars (bringing the total to 100) will be available before the end of the year.

BRITISH WESTINGHOUSE ELECTRIC & MFG. CO. (LTD.)—The Chairman (Mr. J. Annan Bryce) at the meeting on Monday stated that the debit balance of £7,319 from 1909 had been transformed into a credit balance of £5,117, a net gain of £12,436. That represented a small proportion of the increased profits of the business during the year, as, in addition to substantial reserves for unforeseen contingencies in respect of contracts in course of completion, nearly £18,000 more than last year had been written off as depreciation. The trading profit was £112,538, compared with £84,156. The percentage of profit to output was somewhat lower than last year owing to lower prices. The directors, however, hoped that with a continuance of the improvement in trade a higher rate of profit might be realised. The works at Trafford Park and their equipment stood in the books at the close of 1909 at £1,706,516, but at the close of 1910, notwithstanding an additional expenditure of £10,898, they stood at £1,687,439, or a reduction of £19,076. In many respects their works were originally designed on too lavish a scale. When the capital was reduced in 1907 large provision was made to meet that, but since then it had been decided to close down the steel foundry, and for the present they had postponed the idea, then entertained, of building large horizontal gas engines. He mentioned that merely to indicate that before they could enter upon a dividend-paying stage some plan would have to be devised for bringing capital cost to a lower figure. Before making any proposals to that end the directors thought it well to await the result of the appeal in the Underground Railways arbitration. If the result of the appeal was to confirm the award, a very serious loss would have to be faced, and that would be the proper occasion for considering what proposals should be made for writing down capital. The contract out of which this trouble had arisen was made at the very beginning of their career, and no responsibility for it attached to the present board or staff. Shares and debentures in other companies (£286,414) were slightly less than before. The main items were their holdings in the Clyde Valley Electrical Power Co., the Traction and Power Securities Co. and the Mersey Railway Co. They had recently sold their debentures in the Mersey Co. at a profit over the price at which they stood on the books. The Clyde Valley Co. had considerably further improved its position within the past year, and there was every indication that before very long it would be in a dividend-paying condition. The Mersey Company showed year by year a steadily-increasing net revenue. The directors continued their endeavours to expand the company's existing lines of manufacture and to add new lines where it seemed that those could be developed advantageously in conjunction with their existing business. The expansion of the business in steam turbines had been particularly satisfactory. They altered the design of their turbines about two years ago, when a licence was acquired for manufacturing under the Rateau patents. They had installed, and were at present installing, large numbers of these machines both at home and abroad for important railways and corporations. The company's position in that important line of business was stronger than it had ever been, and the directors looked forward to continuous development in that direction. The volume of

Digitized by Google

business during the current year had, so far, been satisfactory, and there was no appearance of any slackening in trade.

In the course of the discussion which ensued, Mr. H. W. BIRKS referred to the disappointing history of the company, and said that the constant changes on the board were matter for regret. Only one year since the formation of the company had passed without there having been secessions from the board of one kind or another. Those continued changes created a bad impression. He inquired what was the worst which could happen to the company in connection with the arbitration award.

The CHAIRMAN, in reply, said that Mr. Carlton when he came to this country arrived at the conclusion that it would be desirable gradually to alter the character of the directorate by having fewer American and more English directors. Accordingly the American directors had from time to time disappeared from the board. He realised that Americans coming here were at a disadvantage in not understanding the methods of conducting business in this country. With regard to the arbitration, if they lost the case it would involve the company in a sum of £100,000 and about £20,000 for costs.

The motion was agreed to.

CITY OF SANTOS IMPROVEMENTS CO. (LTD.) At the meeting last week Mr. D. M. Fox said the results for 1910 were satisfactory notwithstanding the vexatious delay in the matter of the definite contract with Camara Municipality for the complete electrification of the system of tramways in Santos. They had now signed a contract for 40 years. It was also gratifying to find that the effect of the partial electrification of the tramways (15 miles out of 34 or thereabouts), with the improved and more rapid service, had already resulted in a great impulse being given to the construction of new and more modern houses along the tramway routes. They were able to pay a final dividend of 4½ per cent., making 7 per cent. for the year, leaving £4,746 to be carried forward. The tramways had been worked during the year under abnormal conditions, partly by animal and partly by electric traction. The results of working the electrified system had been most encouraging. The number of passengers carried was 9,150,000, an increase of 770,000. £220,000 was the estimated cost of electrifying the tramways and matters incidental thereto. Mr. Dawbarn (of Messrs. Mordey & Dawbarn, the company's consulting engineers), with an assistant engineer, left for Santos on March 31 to start the works and to come to an understanding on all engineering points with their resident engineer (Mr. H. M. Sayers), under whose immediate superintendence the works would be carried out. In Mr. H. M. Sayers they had an experienced and capable engineer, to whom they entrusted the works with every confidence. He had not been long in the company's service, but he had had considerable experience in executing similar works. It was to be expected that the whole of the work would be completed well within the time stipulated.

CITY OF BIRMINGHAM TRAMWAYS CO. (LTD.)—At the meeting on Monday Mr. Emile Garcke congratulated the shareholders on the unique position occupied by the company, as it was a tramway company whose lines were gradually passing over to the local authorities, its receipts had year after year shown increases, and its net profits had improved. The gross receipts last year were £180,000, against £172,000 in 1909, and the net profits (after paying interest and preference dividends) amounted to £44,327, against £38,516. They were again paying 10 per cent. on the ordinary shares, and transferring to reserve £36,513. They were nearing the end of their prosperity as a tramway company. Out of the 18 miles which they were working in the City of Birmingham and the vicinity more than half would go out of their hands and pass over to the local authorities at June 30, and out of the remaining mileage six miles were in Aston, which were being worked by the company without profit. After June 30, therefore, their profits would undergo a heavy diminution, and their expenses would be relatively large. The present position of the company from a revenue-earning point of view, was likely to continue satisfactory.

COVENTRY ELECTRIC TRAMWAYS (LTD.)—The gross profit for 1910 was £12,469, against £9,621 in the previous year. Deducting debenture interest and London office expenses, the net profit was £9,570, or with amount brought forward £10,016. The directors recommend that £2,500 be appropriated for depreciation and £7,475 to payment of 5% per cent. dividend on the share capital. The cars carried 5,076,278 passengers, against 4,597,648. Five new cars were added.

The Corporation of Coventry have given notice to acquire the undertaking.

CRAIGPARK ELECTRIC CABLE CO. (LTD.)—The net profit for the year ended March 31 was £6,245. 6s. 1d. and £671 was brought forward. After payment of the preference dividend for the year a dividend at the rate of 6 per cent. on the ordinary shares for the year is recommended.

CUBA SUBMARINE TELEGRAPH CO. (LTD.)—For the half-year ended Dec. 31 the total receipts were £18,351. 5s. 11d., and expenses were £6,672. 15s. 4d., leaving £11,678. 10s. 7d., added to £7,397. 1s. 7d. brought forward, making £19,075. 12s. 2d. £2,000 has been placed to reserve against loss on investments, and £2,000 added to the reserve fund, which now stands at £120,000. The preference dividend absorbs £3,000, and leaves £12,075. 12s. 2d. The directors recommend a dividend at the rate of 6 per cent. on the ordinary shares (free of income tax), the balance (£7,275. 12s. 2d.) being carried forward. The cables continue in good working order. Mr. James Scott, for reasons of health, having asked to be relieved of the active duties of secretary, Mr. Albert Charles Austin, the assistant secretary, has been appointed secretary, and Mr. Scott's services have been retained in a consulting capacity.

DEUTSCH-ATLANTISCHE TELEGRAPHENGESELLSCHAFT.—In the note which appeared in THE ELECTRICIAN of April 21 (p. 75), giving the details of this company's report for the year 1910 there was an omission which should be rectified. After the words "after meeting working expenses" there should be inserted "applying M.595,954 for amortisation of cables and M.127,885 for writing off."

ELMORE'S GERMAN & AUSTRO-HUNGARIAN METAL CO. (LTD.)—The accounts for 1910 show that the debenture stock now stands at £75,845, and the loan to the Metall Co. has been reduced to £49,932. 14s. 7d. The progress made by the Metall Co. resulted in an increase in the sale of finished goods of nearly 300 tons, or 11 per cent. over 1909. M.160,198 (£7,814. 10s. 9d.) was expended during the year upon additions and extensions and it has been possible to still further reduce the cost of production. The profits of the Metall Co. were lower by M.100,180·80, in spite of reduced cost of production, owing to a price war in Germany since 1910. The Mertens printing process is being developed, and important newspapers in Germany and France have purchased licences. Rollers have already been delivered, but a regular demand will only be possible after the delivery and erection of the necessary printing machines; such delivery has now commenced, and the directors believe that a new and remunerative branch of business will be created. The profits of the Metall Co. not being sufficient to permit of payment of a dividend upon its shares, the accounts of Elmore's Co. show a loss of £5,333. 19s. 9d.

LA PLATA ELECTRIC TRAMWAYS CO. (LTD.)—The accounts for the year 1910 show, after paying debenture interest, a balance of £4,148.

The CHAIRMAN (Mr. W. F. Hamilton, K.C.) stated at the meeting on Tuesday that the total receipts in La Plata were £34,483, of which £21,691 had been derived from electric traction. That was satisfactory considering the abnormal conditions prevailing during the past year and the great interruptions to traffic caused by the construction work, &c. On the electric sections the takings had averaged 1s. per mile run, and the expenses averaged 67·5 per cent. of the receipts, which would bring the expenditure on the electric sections up to 8d. per mile run.

MERTHYR ELECTRIC TRACTION & LIGHTING CO (LTD.)—The total revenue for 1910 was £19,253, against £18,105 for the preceding year. The expenses were £11,034, compared with £10,540. After deducting expenses and charging profit and loss account with £1,500 for provision for renewals, the total surplus is £5,070. The directors recommend that £1,000 be placed to reserve, and after payment of preference dividend, a dividend of 6 per cent. on the ordinary shares for the year (£1,800) is recommended to be carried forward. The gross receipts from the electric supply section of the undertaking were £8,089, and working expenses £2,632. The total number of units supplied was 858,625, against 740,952 in 1909. The number of units sold for lighting and power was 464,865, compared with 352,782 units for 1909, an increase of over 31 per cent. Having obtained the consent of the Board of Trade to the erection of overhead mains, the company is now giving a supply for the public lighting of the whole of Dowlais, under agreement with Merthyr Corporation, and the mains are also being used for private supply. The gross receipts from the light railways were £11,042, a decrease of £21.

RIO DE JANEIRO TRAMWAYS CO. (LTD).—The revenue for 1910 was $5,433,576, and the surplus is $2,337,142, added to $1,707,935 brought forward, making $4,045,078, out of which $250,000 has been applied to sinking fund for first mortgage bonds, $300,000 transferred to reserve, two quarterly dividends of 1 per cent. each and two of 1½ per cent. each have been paid, and the balance ($2,032,640) carried forward.

CITY NOTES.

MEMORANDA (May 4).—**Bank rate 3 per cent.** (March 9, 1911). **Price of silver,** 24⅞d. per oz. **Consols** 81¼—81¼ **for money;** 81⅜—81⅝ **for account. Consols Pay Day, June 1; Stock and Shares Continuation Days, May 10 and 29; Ticket Days, May 11 and 30; Pay Days, May 12 and 31; Mining Shares Carry Over Day, May 9.**

PRICES OF METALS (London).—*Copper*, **cash,** 54⅞; three months, 54⅝. *Lead*, **English.** 13¼—13⅜; **foreign,** 12⅛—12⅝ cash, 12⅝—12⅞ three months. *Spelter*, 24¼ cash, 24⅜ three months. *Tin*, **English,** 191—192; **foreign,** 193 cash, 189¾ **three months.** *Iron*, **Cleveland, cash,** 46/0½, **three months,** 46/9.

EASTERN TELEGRAPH CO. (LTD.)—Subject to final audit, the accounts for the year ended Dec. 31, 1910, show that after making a contribution to general reserve fund, payment of interest on the 4 per cent. mortgage debenture stock, dividend on the 3½ per cent. preference stock and three interim dividends of £1. 5s. per cent. each on the ordinary stock to Sept. 30 last, there is a balance available out of which the directors recommend payment of a final dividend of £1. 5s. per cent and a bonus of £2 per cent. (both tax free) and payable on May 17 inst., making, with previous payments on account, a total distribution of 7 per cent. on the ordinary stock for the year 1910. The transfer books of the ordinary stock will be closed from 10th to 17th inst. inclusive.

EASTERN EXTENSION AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.)—Subject to confirmation by the shareholders, the directors have declared a dividend for the quarter ended Dec. 31 last of 2s. 6d. per share, together with a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for 1910, payable 17th inst. The share register will be closed from 9th to 16th inst.

WEST INDIA & PANAMA TELEGRAPH CO. (LTD.)—Dividends are announced of 6s. per share on the first preference shares (for six months), 6s. per share on the second preference shares (for six months) and 1s. 6d. per share on the ordinary shares, tax free. For the first half of the year 1s. per share was paid, and at the same time the arrears on the second preference shares were cleared.

THE ELECTRICIAN:

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY, SCIENCE AND FINANCE.

ESTABLISHED, First Series (Weekly), 1861; Second Series (Weekly), 1878.

No. 1,721. [No. 5. Vol. LXVII.] FRIDAY, MAY 12, 1911. PRICE ONE SHILLING NETT. (by post 1s. 0½d.) *Abroad extra.*

CONTENTS OF THE CURRENT NUMBER.

Notes 161
Arrangements for the Week .. 164
The Sixth Edition of the I.E.E. Wiring Rules 165
Practical Aspects of Printing Telegraphy. By Donald Murray, M.A. Illustrated. Concluded 166
Reinforced Concrete Electric Lamp Poles. By L. C. Sabin. 170
Electrification of the London, Brighton & South Coast Railway. Illustrated 171
The New Ironclad - Exide Battery for Electric Vehicles. By L. H. Flanders 173
The New Wiring Rules 174
Reviews 175
A History of the Cavendish Laboratory; Reviewed by R. S. Whipple. Electric Circuit Problems in Mines and Factories [Crapper].
The Driving of Winding Engines by Induction Motors. By H. J. S. Heather. Illustrated 176
Correspondence 179
Accumulators and Portable Photometers (Clayton H. Sharp and A. P. Trotter).
Conference on Education and the Training of Engineers.. 180
Soirée of the Royal Society .. 180
The Bruston Automatic Electric Lighting System. Illus. 181
Electrical Trades Benevolent Institution 181
Legal Intelligence 182
Municipal, Foreign & General Notes..... 186
Trade Notes and Notices .. 188
Companies' Meetings and Reports 190
City Notes 192
Companies' Share List 193

THE SPECIAL MINING ISSUE is published (gratis to subscribers) with this number of "The Electrician," facing p. 178.

COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

Mine Signalling and Telephony 23
A Useful Mining Switchgear Publication 26
Niclausse Automatic Stokers 26
"Twinbreak" Ironclad Switch. Illustrated 27
Mining Pillars. Illustrated 30

NOTES.

National Insurance.

Everyone possessing a spark of humanity must deplore the fact that sickness and unemployment bring misery to those of limited means. We all welcome with open arms any well-conceived attempt to ameliorate this almost inevitable condition of things. But, however humanitarian we may be, it is essential that we should realise that unemployment and poverty are closely allied with the advance of civilisation and the progress of the world. The production of national wealth depends upon individual effort and the profitable employment of capital; and in any attempt to reduce poverty and suffering, great care must be taken that the remedy is not worse than the disease, and that the conditions we deplore are not aggravated and extended. This is the greatest danger in the present-day attempts at humanitarian legislation—that Parliament may so rob the home investor of every reasonable possibility of an adequate return upon his investment, as to take the edge off his keenness for speculation. The late Sir William Harcourt used to say that we were all "socialists." If he had lived in 1911 he would probably have said we were adding sentiment to our socialism. Therein lies the danger.

It is unfortunate that we must of necessity consider the economic dangers in front of any such proposals as those put forward by Mr. Lloyd George. The path of the employer, however, is increasingly difficult. What with the State scheme of non-contributory old age pensions and its burden upon industrial profits; the keener-than-ever competition of our oversea trade rivals; the generally increasing cost of raw material; and now the direct contribution towards the cost of sickness and insurance of employés (whether the need exists or not), it seems that the last straw has been added to the already heavy burden of the industrial employer. We are sure the employer is no less humanitarian in his feelings than Mr. George, but he has already either a difficulty in satisfying the reasonable demands of his shareholders or in making both ends meet where he himself is the man who has to "shell out." The constant drain upon trading profits must, it seems to us, in the end destroy the main object of the Parliamentarians and drive the employer to resort to every conceivable device, humane or otherwise, to minimise the effect of these constant calls upon his resources. We believe the latest contribution the employer of labour is called upon to pay will prove the most onerous.

A Conference on Education.

Of all our engineering societies the Institution of Civil Engineers has given most attention to the subject of technical education; and some few years ago, after careful deliberation, a report was issued stating broadly the lines on which such education should be completed. The Council evidently now think that sufficient time has elapsed for the subject to be given further consideration, and consequently a conference dealing with education will be held at the Institution on June 28th and 29th. It is intended to deal with the subject on broad lines and to avoid restricting the discussion to engineers only, and much less to those practising in a particular branch of engineering. This will be clear from the list of names published elsewhere of the officers of the conference. A number of subjects will be

Digitized by Google

discussed and will be introduced by short notes submitted by persons having special qualifications. There are, no doubt, a number of educational questions about which opinions differ very considerably. The system of education at technical colleges is becoming fairly standardised, but it is difficult to know how the education which should follow the college course can be obtained to the best advantage. A natural tendency is for the student on leaving the technical college to obtain a position in which he is paid for his labours, but this is not necessarily the best course. If the conference throws light upon this part of the subject alone it will have served a useful purpose.

Traffic Developments in London.

THE recent announcement that a powerful new company is to be formed with the object of placing on the London streets a large number of motor omnibuses has doubtless come as a surprise to most people; though it is only in keeping with previous experience that, as soon as a company has fair prospects of obtaining even a small return on its capital, other interests should enter the field to compete for the supposed unlimited passenger traffic of the metropolis. After the keen competition that has prevailed during the last few years and the disheartening financial results shown, the existing companies working omnibuses, tramways, and underground railways were doubtless looking forward to less strenuous and more prosperous times, and the improvement in traffic and receipts shown in recent reports gave promise of a more adequate return on the large amount of capital sunk in these enterprises. It seems, however, that the arrival of "The Premier Motor Omnibus Co.," as the new Company is called, is destined to dispel any such hopes. This Company, it is stated, is to operate omnibuses manufactured by the Daimler Co.—who are largely interested in the new venture—and among the features claimed for these omnibuses are:—No change-speed gear, gradual and even start, comparative absence of noise and vibration, and lower floor line.

FOLLOWING the statement of the forthcoming flotation of The Premier Motor Omnibus Co. comes the announcement, on Wednesday last, of an "arrangement" between the London General Omnibus Co. and the companies representing the underground railways, whereby more harmonious working is to result. The issue of interchangeable and through tickets is also under consideration. The London United Tramways, which already work in co-operation with the underground railways, are also involved in the arrangements; so that it is evident a very extensive scheme is on foot. At present a committee, to be composed of two representatives from each of the companies concerned, is being formed to draw up a detailed scheme.

THE London traffic problem has recently assumed a new aspect, owing to the desire of the London County Council to extend their tramway system into the "West End." Although powers are at present merely being sought to extend the track along Edgware-road to Oxford-street, in the neighbourhood of the Marble Arch (a proposed extension of the Battersea lines to the Brompton Oratory having been withdrawn, though possibly only temporarily), the general policy of the Council is becoming plain, and "The Times," in a leading article entitled "The Menace of the Tramways," sees unmistakably the ultimate invasion of Park-lane in order to link up the tramways in the north and south of London. That the matter is considered to be of great importance is evident from the fact that the Home Office have presented a Report to the Parliamentary Committee which has the Council's Bill under consideration. The Report embodies the criticisms of the Commissioner of Police, who points out that the Marble Arch is a most unsuitable place for a tramway terminus. The whole question of co-ordinating the various traffic facilities provided, however, should undoubtedly be considered at once, since delay will merely accentuate the difficulties of linking up. As to the undesirability of tramways in many West End thoroughfares there can be no two opinions, but a subway, as in Kingsway, might perhaps meet the case. In this connection, though the difficulties to be overcome in their construction might render the scheme impracticable, it is interesting to notice that such subways have recently been found necessary and desirable in several American cities.

"The Electrician" Second Mining Issue.

WITH this week's ELECTRICIAN we publish the third of those special issues whose object it is to provide an accurate idea of the position of electrical engineering in its application to certain branches of national activity. Like the first of these, which appeared three years ago, our present special issue is devoted to electricity as applied to mining. In this industry the use of electrical equipment has enormously increased, even in that short period. Not only, too, has the employment of the motor and its kindred apparatus increased, but electrical engineers have, doubtless as a consequence, better knowledge of the conditions under which their machinery has to work in mines; and are now better able to design it for operating under these conditions. In a word, three years has turned theory into practice. This does not mean that there was no practice three years ago, but rather that present-day methods have become much more practical. This is proved by the fact that we are now able to publish an issue dealing with the same subject as that considered three years ago, but dealing with it from quite a different point of view. Although great progress has been made, there is still much to be done, especially in the direction of overcoming prejudice; and because a satisfactory advance has been made in a short time this is no reason for the electrical engineer to rest.

Imperial Conference.

WE learn that it is probable when, at the forthcoming Imperial Conference, the subject of Imperial telegraphic communication is reached, it will be found that the representatives of the Home Government will meet any proposal for discussing the question of submarine cable communication throughout the Empire with an expression of opinion that it would be first desirable to discuss the subject of an Imperial System of Wireless

Digitized by Google

Telegraphy. We understand further that one of the principal members of the present Government takes a keen interest in this question, and that his views are likely to receive the fullest support.

Constantinople Telephone Contract.—The contract in connection with the telephone concession which has been granted to Mr. H. Laws Webb (on behalf of a British syndicate) was formally signed on the 6th inst by Djavid Bey and Mr. Webb, who then left for London.

Newfoundland Cable Landing Tax.—By a majority the Supreme Court have given judgment in favour of the Newfoundland Government in their action against the Commercial Cable Co. for $16,000 yearly as landing taxes. The Company, it is stated by Reuter's Agency, will probably appeal to the Privy Council.

Olympia Electrical Exhibition (1905) Trust Fund—In regard to this fund Mr. W. Davenport has written to us as follows:—

I am pleased to inform you that this Fund has now been realised, and the sum of £378. 12s. 8d. has been paid into the funds of the Electrical Trades Benevolent Institution, and £203. 17s. 7d. to the Benevolent Fund of the Institution of Electrical Engineers. The trustees for this fund were: Sir Wm. H. Preece, K.C.B., E. Cunliffe Owen, C.M.G., John E. Kingsbury, Chas. Spencer Northcote, Jas. E. Edgcome and Walter Davenport.

Fire at Hindhead Electricity Works.—In our last issue we briefly referred to the fire that damaged the electricity supply station at Hindhead early on Wednesday last week. Further particulars which have come to hand show that the station was practically burnt out. Under these circumstances, it is very gratifying to learn that the continuous-current supply was restored in Hindhead on Friday afternoon, whilst the high-tension alternating-current transmission to Haselmere was switched on again by Sunday evening. The greatest credit is due to the staff, the consulting engineers (Messrs. Handcock & Wilkes) and to the manufacturers concerned, for the way in which the supply was made available so soon after the destruction of the station. The promptitude with which the manufacturers supplied spare parts, &c., was particularly noteworthy. Leatherhead Electricity Co. also assisted by loaning a transformer, switchboard, &c. As to the cause of the disaster, it is practically certain that the fire originated from some exploded ignition cells, which appear to have been left charging overnight on a shelf in the disused boiler house (Diesel plant is now used). At any rate, when the engineer arrived on the scene soon after the outbreak, he found the fire firmly established in the roof immediately over this shelf. Although the disaster is, of course, unfortunate, it provides splendid testimony to the way in which an electricity supply can be restored after a station has been practically destroyed by fire.

Cable Interruptions and Repairs.

	Date of Interruption.	Date of Repair
Assab–Perim	July 8, 1909 ...	—
Malta–Tripoli.....	April 20, 1910 ...	—
Lusaka–Palura	May 26, 1910 ...	—
Tourane–Amoy	Sept 25, 1910 ...	—

Kwandang–Menado	April 25, 1911 ...	May 5, 1911.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

In our Second Mining Issue, which is incorporated with the present number of THE ELECTRICIAN, will be found a large number of articles, among the following: "Electricity in Cornish Mines," by Neil Tasker; "The Position of Electricity in Mining in South Africa," by J. Mackness; "The Elimination of Risk in the Use of electricity in Mines," by Prof. W. M. Thornton; "Special Risks in the Application of Electricity to Mining Work under South African Conditions," by H. J. S. Heather; "The Gas-tight and Flame-proof Motor Problem," by Talbot Duckitt; "Public Electric Power Supply to Collieries," by W. B. Woodhouse; "Power Supply from a Private Plant," by W. Bolton Shaw; "Centralisation of Power in Collieries," by W. E. Chappell; "Notes on Switchgear for Use Underground in Mines," by H. W. Clothier; "The Progress of Electric Winding in England," by G. Hooghwinkel; "Coal Cutting," by H. J. Fisher; "Underground Colliery Wiring," by A. B. Mallinson; "Electric Hand Lamps for Collieries," by W. Maurice; "Controllers and Resistances in Mines," by Edmund Garside; "The New Electric Mining Rules—Some practical Considerations"; "The Profitable Use of Waste Heat." A number of descriptive articles also deal with the machinery and apparatus used in mining work.

We give further particulars and illustrations of the electrified section of the suburban system of the London, Brighton & South Coast Railway, including the recently converted Crystal Palace lines. Experimental running has been carried out on the new section during the last week or two.

We conclude our abstract of Mr. D. Murray's Paper on "Practical Aspects of Printing Telegraphy," and an account is also given of the discussion on this Paper at the meeting of the Institution of Electrical Engineers last week.

At the meeting last night a Paper by Mr. H. J. S. Heather on "The Driving of Winding Engines by Induction Motors" was read.

We give an account of the chief alterations in the sixth edition of the I.E.E. Wiring Rules issued last week. The Rules are also discussed in our Leading Article.

Particulars will be found elsewhere in this issue of the "Bruston" electric-lighting plant, the operation of which is entirely automatic.

West Ham Electric Lighting Committee propose to carry out extensions of generating plant, &c., at a cost of £59,000.

The inquiry into the application of Dublin Corporation for permission to borrow £128,129 for extensions of the electricity undertaking was concluded on Saturday.

Parliamentary.—During the week Select Committees of the House of Commons considered the Greater London Railway, the L.C.C. Tramways and Improvements, and the Matlock District Railless Traction Bills.

Legal.—The Railway and Canal Commission commenced the hearing on Tuesday of an application by the National Telephone Co. against the Postmaster-General in respect of notice received under an agreement for the purchase of the Company's undertaking by the Postmaster-General.

At the Glasgow Sheriff Court on Monday arguments were heard in an interesting appeal as to the assessment of the Corporation tramways. Judgment was reserved.

OBITUARY.

MR. E. BOULNOIS.—We regret to record the death of Mr. Edmund Boulnois, who was chairman of the Calcutta Electric Supply Corpn., deputy chairman of the Central Electric Supply Co. and a director of the Westminster Electric Supply Corpn.

PERSONAL NOTES.

Mr. T. Buckley, chief electrician to the New Zealand Telegraph Department, is visiting the United States, England and the European Continent for the purpose of inspecting the telegraph and telephone systems of those countries with a view to reporting to the New Zealand Government as to the adoption of any new apparatus, &c., that he may consider of advantage. Mr. Buckley returns to New Zealand about November.

Mr. Wm. Maurice, of Huchnall Torkard, Notts., has, we learn, resigned the management of the Huchnall Collieries, and is now developing his consulting practice as an expert in the re-organisation of old mines and in the electrification of collieries. Mr. Maurice is well known as the pioneer user of exhaust steam turbines and of the application of storage batteries to three-phase colliery installations. He has also successfully pioneered the machine mining of thin seams in the Leen Valley Coalfield, and on the literary side is the author of "Electric Blasting Apparatus and Explosives" and "The Shot-Firer's Guide," two volumes in "The Electrician" series of standard works.

Mr. H. W. Butler, chief engineer of the Electrical Power Storage Company informs us that he has now resigned his position with the Company and that all future communications intended for him should be addressed to 10, Belsize Park, Hampstead, London, N.W. Mr. Butler has been connected with the E.P.S. Co. for over 26 years.

APPOINTMENTS VACANT AND FILLED.

The Allmanna Svenska Aktienbolaget, Västerås, Sweden, require for their estimating department an electrical engineer with large experience in working out estimates for electrical schemes. See an advertisement.

A switchboard attendant is wanted for a large power station. See advertisement.

The Newcastle & District Electric Lighting Co. (38, Grainger-street West, Newcastle-on-Tyne) require a shift engineer at their Close power station. Commencing salary £2. 10s., rising to £2. 15s. per week. See an advertisement.

A first class electrical engineer is required to take charge of instrument works. See advertisement.

A sales engineer is wanted by Sunderland Corporation electricity department. Salary £156 per annum. Applications to the borough electrical engineer and manager, Mr. Alfd. S. Blackman. See also advertisement.

A London institution of technical education by correspondence require an assistant instructor in electrical engineering. See advertisement.

Manchester Electricity Committee require a shift engineer at Stuart-street generating station. Commencing salary £175. Applications to the Chairman by 10 a.m. May 16.

An electrical engineering firm in Manchester advertise for an assistant chief tester in their instrument and transformer department, also two junior testers.

The Yorkshire Electric Power Co. advertise for a superintendent to undertake the control of the department engaged in laying underground and overhead mains, equipment of sub-stations, &c. Salary £250 per annum. Applications to the Company, Thornhill, Dewsbury.

A lecturer in applied mathematics is required for the Grey University College, Bloemfontein. Salary £400 per annum. Applications to the High Commissioner for South Africa, 72, Victoria-street, London, S.W., by May 19.

The Australian Commonwealth Government require a qualified person to design and superintend the establishment of wireless telegraph stations in Australia at £600 per annum. Applications to 72, Victoria-street, London, S.W., by May 20.

An important firm of electrical engineers require for their London office a junior assistant, with technical training and knowledge of German, for publication work.

Cheltenham Local Higher Education Committee require a director for their technical schools. Salary £220, rising to £250 per annum. Applications to the Clerk to the Governors by May 16.

Sheffield Electri ity Committee have made the following rearrangements of the staff :—

Mr. J. W. Barnes, superintendent of wiring and fittings department, to be commercial assistant, at £350 a year; Mr. C. E. R. Biggin, assistant superintendent of wiring and fittings department, to be superintendent, at £225 a year; Mr. F. E. Meredith, installation inspector, to be meter and testing assistant, at £143; and Mr. J. B. Wilkeley, chief accountant is to have his salary increased to £230 a year. The position of meter superintendent vacant by resignation, is not to be filled.

Mr. C. F. Edwin (A.C.G.I.) has been appointed chief electrical engineer to the Chilian Navy. Mr. Edwin obtained his diploma in electrical engineering in the Central Technical College in 1904. Since that date he has been with Messrs. Siemens Bros. Dynamo Works, having held the position of chief of test house for nearly four years.

Messrs. W. W. Warren and R. A. S. Duncan have been appointed shift engineers at the Greenwich generating station of the London County Council at £250 each per annum.

INSTITUTIONS AND SOCIETIES.

Incorporated Municipal Electrical Association.—A detailed programme of the Convention to be held at Brighton from June 27 to 30 has now been issued. On the first day of the Convention, following a welcome of the Association by the Mayor of Brighton, Mr. J. Christie (engineer and manager, Brighton Electricity Department) will deliver his presidential address, and the following two Papers will be read and discussed: "Electricity Supply viewed from the Municipal Committee's Standpoint," by Councillor H. Leese (Stoke-on-Trent); "Modern Wiring Practice," by Mr. J. W. Beauchamp (chief electrical engineer, Tunbridge Wells). On Wednesday, June 28, the meeting is to take place at the Municipal College, Portsmouth, when a Paper on "Internal Combustion Engines in Power Stations" is to be read by Messrs. H. L. Howard (chief electrical engineer, Barking) and R. M. Carr (chief electrical engineer, Leek). No Papers are down for reading on Thursday, June 29, when the meeting will be held at Brighton, but discussions are to take place on "Purchase of Fuel" and "Street and Shop Front Lighting," the discussions being opened by Mr. C. E. C. Shawfield (chief electrical engineer, Wolverhampton) and Mr. A. H. Seabrook (chief electrical engineer, Marylebone) respectively. The annual dinner takes place the same evening. The annual general meeting is to be held on the Friday morning, also at Brighton. In addition to the above Papers and discussions, visits will be paid to the Southwick power station of the Brighton Corporation, H.M. Dockyard power house, the lighting and tramway power stations of the Portsmouth Corporation, and other works.

Royal Society.—Among the Papers read at the meeting yesterday afternoon were the following: "On a Method of Making Visible the Paths of Ionising Particles through a Gas," by Mr. C. T. R. Wilson, F.R.S.; "The Path of an Electron in Combined Radial Magnetic and Electric Fields," by Dr. H. S. Allen; and "On the Absolute Measurement of Light—a Proposal for an Ultimate Light Standard," by Dr. R. A. Houston.

Royal Institution.—It is announced that the following gentlemen have been nominated as vice-presidents for the ensuing year: The Right Hon. Sir Henry Burton Buckley, the Right Hon. Earl Cathcart, Dr. Donald W. C. Hood, Mr. H. F. Makins, Sir Francis Laking, Bart., Mr. Alexander Siemens, Sir James Crichton-Browne, F.R.S. (treasurer), and Sir William Crookes, F.R.S. (honorary secretary).

Institute of Metals.—A general meeting of this Institute is to be held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., to-day, when the Second May Lecture will be delivered by Dr. G. T. Beilby, F.R.S. (President of the Institute of Chemistry), on "The Hard and Soft States in Metals." The chair will be taken at 8:30 p.m. by Sir Gerard Muntz, Bart., President of the Institute.

Institution of Civil Engineers.—The "James Forrest" Lecture will be delivered on Wednesday, June 28th, at 9 p.m., by Dr. F. H. Hatch, the subject being "Gold Mining in the Transvaal."

ARRANGEMENTS FOR THE WEEK.

FRIDAY, May 12th (to-day).

PHYSICAL SOCIETY OF LONDON.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "Stream Lines Past the Elliptic Cylinder and Magnetic Interpretation," by Sir George Greenhill, F.R.S., and Col. R. E. Hippisley, R.E. "The Method of Constant Rate of Change of Flux as a Standard for Determining Magnetisation Curves of Iron," by Messrs. J. T. Morris and T. H. Langford; and "Demonstration of a Electric Thermo Regulator," by Prof. H. L. Callendar, F.R.S.

INSTITUTE OF METALS.

8:30 p.m. Meeting at the Institution of Mechanical Engineers Storey's Gate. Lecture on "The Hard and Soft States i Metals," by Dr. G. T. Beilby, F.R.S. Second May lecture.

SATURDAY, May 13th.

BIRMINGHAM AND DISTRICT ELECTRIC CLUB.

7 p.m. Meeting at the Colonnade Hotel, New-street, Birminghan Paper on "Exhaust Steam Utilisation for Generating Electricity," by Mr. V. E. Walters.

TUESDAY, May 16th.

SCOTTISH SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEER

7.30 p.m. Annual General Meeting at 207, Bath-street, Glasgow.

THURSDAY, May 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at Victoria Embankment. Paper on "Automat Telephone Exchange Systems," by Mr. W. Aitken.

FRIDAY, May 19th.

ROYAL INSTITUTION.

9 p.m. Discourse on "Recent Experiments with Invisible Light by Prof. R. W. Wood.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding: Lieut.-Col. H. M. Leaf.

The following orders have been issued for the current week :—

Monday, 15th, "A" Company.—Infantry Drill 7 to 7:30 p.m. Techni Drill 7:30 to 10 p.m.

Tuesday, 16th, "B" Company.—Technical Drill 7:30 to 10 p.m.

Wednesday, 17th, All Companies.—Annual Course of Musketry at P fleet Ranges. A list of trains and other detail can be obtained Headquarters, also railway tickets for officers, N.C.O.s and men atter ing the shoot.

Thursday, 18th, "C" Company.—Recruits Drill (Infantry Drill) 6:45 7:30 p.m. Technical Drill 7 to 8:15 p.m. Company Drill 8:20 to 9 p. (Millbank Barracks, Drill Order).

Friday, 19th, "D" Company.—Recruits Infantry Drill 7 to 8 p Technical Drill 7 to 10 p.m.

All Companies.—Annual Course of Musketry, detail as for Wednesd the 17th.

Digitized by Google

THE SIXTH EDITION OF THE I.E.E. WIRING RULES.

The sixth edition of the Wiring Rules of the Institution of Electrical Engineers, which was issued last week and is dated April, 1911, has been expected for some time past. In revising this new edition the Wiring Rules Committee have had the assistance of the Cable Makers' Association and the Engineering Standards Committee. An exhaustive series of tests has also been carried out at the National Physical Laboratory on the temperature rise of conductors.

We propose here to enumerate briefly the chief features of the new Rules.

In the first place reference is made to the Board of Trade Regulations (1910) for medium pressures (250–650 volts), for the additional requirements of those places which do not come within the Home Office Regulations for factories and workshops.

Two new definitions are included, "bare" and "switchboard" being defined. Among the General Regulations applying where the pressure does not exceed 250 volts, a new rule states that "where the supply for heating or power is likely to interfere with the lighting, separate main supply fuses are desirable." The maximum current to be carried by incandescent lighting sub-circuits has now been raised from 5 to 6 amperes, whilst the maximum number of points on any sub-circuit must now not exceed 10. In the case of earthing, an earth conductor of No. 14 S.W.G., or equivalent section, is specified for every 50 amperes of working current or part thereof. Earthing conductors must be protected against mechanical injury.

A new rule states that in bathrooms special precautions must be taken to prevent the possibility of personal contact with any part of the system. Similar precautions must also be taken in respect of portable lamps where danger would exist, as in damp places.

Conductors (Size and Conductivity).—In calculating the size of conductors it is no longer necessary to assume that at least 5 watts may be consumed at any point. The permissible drop in pressure for lighting circuits must now not exceed 2 per cent. *plus* a constant allowance of 1 volt, subject to the currents given in the Table not being exceeded. This determines the minimum size of conductor; whilst for power and heating circuits the rise of temperature (20 per cent. F.) is the determining factor.

The Table giving the maximum permissible currents for the various sizes of conductors has been considerably altered. In general, it may be said that a very large increase has been made in the permissible current carried by small conductors; but, on the other hand, the maximum allowable current of large rubber insulated conductors has been reduced. Thus, whilst a 7/18 S.W.G. conductor has now a minimum carrying capacity of 5·2 amperes, instead of 4·2 amperes, in the case of both rubber insulated and paper or fibre insulated cables, a conductor having a nominal sectional area of 1 sq. in. has now a maximum permissible capacity of 595 amperes in the case of rubber insulated cables and 932 amperes in the case of paper or fibre insulated cables, as against 750 amperes for both types of cable in the previous edition of the Rules. Attention may be called to the fact that the carrying capacity of rubber insulated cables is now distinguished from that of paper or fibre insulated cables, separate columns for each class of conductor being included in the Table. Up to a size of 7/22 S.W.G., however, both types of insulated conductor have the same maximum capacity, but above this size larger currents are permitted with paper and fibre cables, the difference amounting to more than 50 per cent. in the case of the largest conductor mentioned above.

As regards other features of this Table, the minimum insulation resistance per mile has been reduced, in the case of vulcanised rubber cables for 250 volts pressure, from 2,000 megohms to 1,650 megohms; but for 1/16 S.W.G. and larger conductors the minimum insulation resistance remains unchanged. Flexible conductors have been omitted from the Table.

Insulation.—It is interesting to notice that the pressure test on insulated conductors has been reduced from 2,000 to 1,000 volts, whilst no mention is made of alternating current or frequency. The test for flexible cables is unaltered.

Wiring.—More space is given in the new Rules to methods of fixing the conductors, and the various methods are treated in separate sections. Where tubes with a polished inner surface are used, braiding is stated to be optional. As most attention is likely to be paid to the section dealing with metal conduits, we give this in its revised form.

ENCLOSED WIRING—METAL CONDUITS.

49. Conductors (excepting flexibles) insulated as in Classes A and B (para. 38) may be enclosed in steel conduits with details and accessories in accordance with the British standard specification for "Steel Conduits for Electrical Wiring" or in brass or copper conduits, which must comply with the following conditions:—

a. They must be electrically and mechanically continuous throughout. Plain slip sockets do not comply with this Rule, some form of screwed or grip joint having a conductivity equal to that of the continuous tubing being necessary.

b. At the outlet points of switches, boxes and fittings the ends of the conduits must either terminate at metal outlet boxes or they must socket into blocks, preferably of incombustible material. The conductors must in all cases be mechanically protected up to the fitting.

c. They must have all free ends bushed to prevent abrasion, except where wide bell-mouths are used.

d. They must be connected to earth (paras. 26, 27 and 28). In dry places isolated single lengths of tubing need not be earthed if adequately enamelled or otherwise insulated externally.

e. In damp places they must be watertight.

f. They must be efficiently drained if liable to internal condensation.

g. Sharp bends or elbows are prohibited, but inspection elbows are permissible.

The only new Rule as regards wood casing is the provision that "where the size of the conductor is larger than that of 7/19 S.W.G. sharp bends must be avoided". Where flexible conductors are used for open wiring, they must not "be carried unprotected within 4 ft. of the floor level." They must also be firmly supported, and, unless protected by conduits, must be attached to insulators. The supports must be spaced not more than 3 ft. apart. Flexible conductors must also be without joints, except in junction boxes. The lead covering of lead-covered conductors must be connected to earth.

Earthed Concentric Systems.—The Rules now deal more fully with concentric wiring. The following are the main points to be noted:—

59. Earthed concentric wiring may only be used when connected to systems:—

a. Supplied through double-wound transformers so as not to be in metallic connection with the general system of supply; or

b. In which the use of earthed concentric wiring has been approved by the Board of Trade; or

c. Having their own independent generating plant.

60. Every system must be protected by a single-pole switch or switch-fuse under the control of the consumer, and it must be easily accessible, and placed as near the generator or point of entry of the supply as circumstances permit.

61. Subject to para. 33*a*, the drop in volts on the external conductor from the point of earthing to the farthest lamp must not exceed 7 volts when the maximum current is in use.

62. The earthing shall take place at the point where the earthed concentric system begins—that is to say, at the main switch or switchboard.

63. From the point where the system is earthed the concentric system of wiring must be employed throughout up to the fixed outlet points for fittings. Twin flexibles may be used beyond this point.

64. All joints in the external conductors must be of such a nature that the conductivity of the conductor is not reduced.

65. Transformers, motors, arc lamps and all consuming devices must be controlled and protected as in two-wire systems, but only on the internal conductor. Only single-pole switches and fuses may be used, and no switches, fuses or circuit-breakers may be placed in the external conductor.

All ceiling roses, switches, plug connectors and outlet points must be so mounted that the external conductor is interposed between the internal conductor and the surface upon which the fitting is mounted. This does not prevent the ordinary wooden block being interposed between a metal plate and the ceiling rose, switch or plug connector.

66. Ordinary connectors, lamp holders and ceiling roses may be used. If screw socket lamp-holders are used, the centre contact of the lamp-holder must be connected to the internal conductor.

67. Fittings supporting lamps may be wired with two wires, one wire being insulated and connected to the internal conductor. The metal

Digitized by Google

work of the fitting must be electrically connected to the external conductor.

68. The fuse board must be provided with either—

a. A metal case to which the external conductors leaving the board must be connected; or

b. A metal bar or wires connected to the external conductors, the whole being connected to a sheet of metal of the same size as the board, which is to be interposed between the board and the wall or surface on which it is to be mounted.

Switches and Circuit-breakers.—The new Rules stipulate that switches and circuit-breakers "must be so constructed or arranged that they cannot accidentally fall or move into contact when left out of contact." Maximum circuit-breakers must also be arranged effectively to interrupt the current before it so exceeds the working rate as to involve danger. According to the previous edition of the Rules, metal covers of switches for more than 5 amperes, at pressures over 125 volts, had to be lined with insulating material. The limiting current has now been raised to 6 amperes.

Fuses.—The rule as to the overload to be carried by fuses has been modified and reads as follows:—

They shall effectively interrupt the current when a short-circuit occurs, and they must be so proportioned to the current to be carried that no conductor protected by them can be raised in temperature above that specified in para. 37. When the working current does not exceed 10 amperes, the fuses must be proportioned to interrupt the current before or when the current through the conductors rises to three times the working current: for working currents above 10 amperes the fuses must be proportioned to interrupt the circuit before or when the current through the conductors rises to twice the working current. The use of fuses of the enclosed type is recommended. No fuse smaller than one having a working capacity of 3 amperes, to fuse at 9 amperes, need be inserted for sub-circuits.

Plug Connectors.—A combined switch and plug connector is stated to comply with the requirements.

Lampholders.—A lampholder must not be in metallic connection with the guard or other exposed metal work of a portable hand lamp.

Incandescent Lamps.—The use of cord grips is recommended, and especially for large lamps it is advisable that the conductors be spaced apart.

Heaters.—Portable heaters must have at least one section controlled solely on the live side of the connector. Where non-luminous heaters are liable to cause danger when left in circuit, a red pilot lamp is desirable.

Motors.—The only changes are that no-volt releases are not now stipulated for alternating-current motors, and that large motors apparently need not have linked circuit-breakers on the conductors.

Accumulators.—Portable accumulators with celluloid cases must be so arranged and placed during re-charging that if they become ignited the fire cannot spread.

The Board of Trade Regulations (1910) for medium pressures, so far as they relate to conditions intended to be covered by the Wiring Rules, are reprinted, as well as the Home Office Regulations for factories and workshops.

PRACTICAL ASPECTS OF PRINTING TELEGRAPHY.*

(*Concluded from p.* 138.)

BY DONALD MURRAY, M.A.

Summary.—The author first discusses the field for printing telegraphs. Their use is chiefly in connection with land lines between centres of population, and they will assist materially the co-operation between telegraph and telephone. He next gives a detailed account of the difficulties encountered in connection with the development and practical application of printing telegraphs, and finally describes the Murray automatic system and the new Murray multiplex system.

PART III.—(THE MURRAY PRINTING TELEGRAPH SYSTEMS.)

To illustrate some methods by which the foregoing difficulties have been more or less overcome, an account is given of the Murray printing telegraph systems. Brief reference only is made to the Murray automatic system, as it has already been described in the Paper on "Setting Type by Telegraph."†

It may be explained in the first place that the Murray printing telegraph systems form a complete printing telegraph organistion, and that they comprise the Murray automatic page-printing telegraph and the Murray multiplex page-printing telegraph, which have been designed to work together as one whole, the automatic system being best suited for long lines, and the multiplex for lines of average length. Many of the instruments are the same in both systems, and are interchangeable, the same alphabet or code of signals—the 5-unit Baudot—being used in both. An important point is that the same keyboard perforator is used on both systems.

In the Murray automatic system, the messages are first perforated on a strip of paper tape in the Baudot 5-unit alphabet. The perforated tape is then used to transmit the messages by means of an automatic transmitter working on the principle of the Jacquard loom. The speed of transmission of the signals is from 100 to 180 words (600 to 1,080 letters) a minute, and at the receiving station the arriving signals are recorded at the same speed as perforations in a second paper tape, which is an exact replica of the transmitting tape. This reproduced tape at the receiving station then serves to operate an automatic typewriter somewhat on the principle of a mechanical piano. The telegraph line is worked duplex, giving one transmission in each direction simultaneously on the one wire. The received messages are printed in Roman type in page form, at speeds ranging up to about 200 words a minute (20 letters a second). The keyboard perforator, automatic transmitter and receiving perforator were described in the previous Paper, and there has been no substantial alteration in the construction of these instruments, although there have been many improvements in detail. In the automatic printer a great improvement has been made by the construction of a high-speed typewriter specially designed by the inventor of the system to suit the automatic selecting mechanism. The essential feature of this typewriter is that the typebars are very short, only 2 in. long from the pivot to the type. This ensures extremely high speed. It is the shortest typebar ever put into a typewriter, the average length of typebars in typewriters being from 3 in. to 4 in. As the moment of inertia varies as the cube of the length of the typebars, the gain in speed is from three to eight times. The typebars are provided with ball-bearings, to ensure free movement and permanent alignment. The typebars being so short, it was necessary to arrange them in a complete circle in order to get room for the required number of 51 characters. As it was very desirable that the operator should be able to see the printing as it proceeded, the circle of type had to be arranged in a vertical plane. Key levers were omitted, as the inertia of key levers interferes with high speed. There are no other special features beyond the fact that the machine is built with unusual strength to stand the strain of the high speed.

In the Murray automatic printer, the letter, line and column feeds are entirely automatic, but the page feed is manually operated, this having been found sufficient for present requirements. The maximum speed that has been reached on this printer is 250 words a minute (25 letters per second). The speed might perhaps be pushed up to 300 words a minute, but the wear and tear would probably be great.

In order to prevent interruption of traffic by any stoppage of the apparatus, it is necessary to have reserve machines. With an automatic system this means duplicating the whole of the apparatus. The result is that the Murray automatic system is very expensive, costing at present about £1,200 per circuit, exclusive of royalites. This is a very serious handicap.

Taking the four factors already referred to—namely, saving of time, labour, line and office equipment—the Murray automatic system shows to advantage only in respect of saving of line. On long lines, 1,000 miles and over, the saving of time and labour are of much less importance than increase in the carrying capacity of the line. This is the case, for instance, in Russia and other new countries. It is in such conditions that the Murray automatic has decided advantages, as follows: (1) The alphabet or code of signals that it employs, and the manner of employing it, result in less signalling time per letter than in the case of any other sytem. (The ratio is approximately 5 for the Murray automatic compared with 6 for the Murray and the Baudot multiplex systems, and 8 for the Morse alphabet.) (2) Synchronism is not employed, only isochronism. (3) Governing or control of speed is very quick. (4) The Murray automatic apparatus is simple. (5) It works very well through the simplest of all repeating stations—namely, the Wheatstone duplex. (6) It works very well and easily with the duplex balance, even on very long lines. Hardly any of these advantages are of importance on short lines.

Murray Multiplex Page-Printing Telegraph.—It is only about a year since this system passed out of the laboratory stage and arrived at practical success. The Murray automatic system may be said to be based on the Wheatstone automatic transmitter. In a multiplex system the instrument corresponding to the Wheatstone automatic

† "Journal" of the I.E.E., Vol. XXIV., p. 555, 1905.

Digitized by Google

transmitter is the distributor, and the Murray multiplex system may similarly be said to be founded on the Baudot, because it has taken the Baudot distributor as its basis. For driving the distributors, however, instead of the Baudot arrangement, the Delaney multiplex plan of using the Lacour phonic wheel motor is adopted. Apart from the distributors, the only resemblance between the Baudot and the

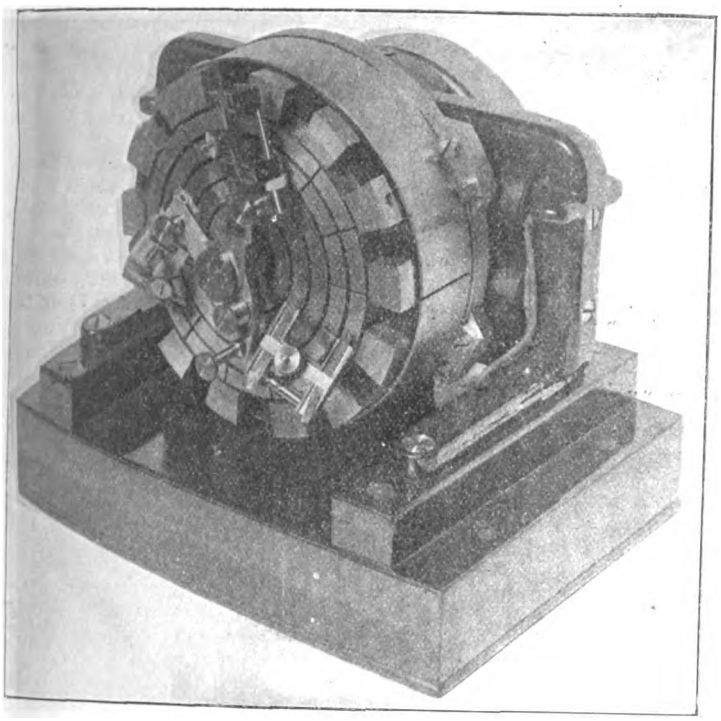

Fig. 1.—Front View of Murray Multiplex Distributor.

Murray multiplex is in general principles and in the use of the Baudot cabinet.

Like the Baudot and similar systems, the Murray multiplex printing telegraph divides up the line time so as to give several transmissions or channels on one telegraph wire, each at a comparatively low speed suitable for the work of one operator sending and one receiving. Two distributors, identical in design, are employed, one at each end of the telegraph line (station A and station B). The distributor at station A sends out a governing impulse once for each revolution of the contact arm. This impulse controls the speed and phase of the distributor at station B so as to keep it running in synchronism with the distributor at station A. The distributor used in the Murray multiplex is shown in Fig. 1. This instrument is a "double," giving two simultaneous transmissions working simplex and four when working duplex. The new system may also be worked "triple" or "quadruple," the duplex balance in these cases giving 6 or 8 transmissions simultaneously on one line.

The distributor brush arms are carried directly on the spindle of a phonic wheel motor, which is identical in all respects with the phonic wheel motor employed in the Murray automatic system, and it is driven in the same way by a vibrating reed. There are no gearwheels or governing mechanisms. The commutator and contact arms and brushes are the same as in the Baudot, and the adjustments are the same. It has the advantage over the Baudot of being simpler, cheaper and easier to construct. On the other hand, where Baudot distributors are already in use the Murray multiplex transmitting and printing mechanisms will work excellently with the Baudot distributors.

The theoretical arrangement of the electrical connections in the Murray multiplex is shown in Fig. 4. One of the transmitting channels of segments of the distributor and revolving contact brush are shown at each station. For the sake of clearness the other segments for the other transmissions on the same telegraph line are omitted, and for the sake of simplicity the Baudot five-key transmitter shown at station A. Also at station A the vibrator and the wheel that keep the contact brush of the distributor revolving are omitted. Various permutations of five positive and negative impulses are transmitted into the line as the distributor arm revolves.

A typewriter keyboard mechanism to operate these five contacts can be easily designed. In one machine made by the author for use with the Murray multiplex there is a cadence magnet which locks and unlocks the keys to enable them to be depressed at the right moment. There is also a letter-counting magnet, which rings a bell at the end of each line of about 60 letters. This is a first-class instrument of its kind, simple, strong and cheap to make; but as the result of careful practical trials by the British Post Office, automatic tape transmission was found to be so much superior to direct transmission that direct transmission was abandoned altogether, so far as the Murray multiplex is concerned.

Actual trial between London and Birmingham for several weeks showed the advantage of automatic tape transmission over direct transmission to be as follows: (1) The output of messages per operator per hour is practically doubled as compared with direct transmission. (2) There is less nerve strain on the sending operators, because there is no cadence to be observed. (3) Much more skill is required to work on the direct cadence keyboard than on the keyboard perforator. (4) Provision is made for quick and invisible correction of errors before transmission in the case of the indirect method of tape transmission in the Murray multiplex. Practical experience has shown that this is a valuable feature with page-printing. The trials were made at 40 words a minute instead of the normal Baudot speed of 30 words a minute, the increased speed being one of the advantages gained by the use of a typewriter keyboard.

The instruments used in the Murray multiplex for tape transmission are shown in Fig. 4. On the right, at A, is a keyboard perforator identical with that used in the Murray automatic system. The tape passes from the perforator into an automatic transmitter, B. This is the same as the tape-feeding mechanism of the Murray automatic printer, except that the tape-feeding mechanism is driven in this case by a magnet instead of by a cam. After running through the automatic transmitter the tape passes on to an automatic tape-winder, C. This instrument is of a very simple character and is entirely automatic. Both sides of the tape may be used, so that the cost of the tape is small. As the automatic transmitter runs steadily at 40

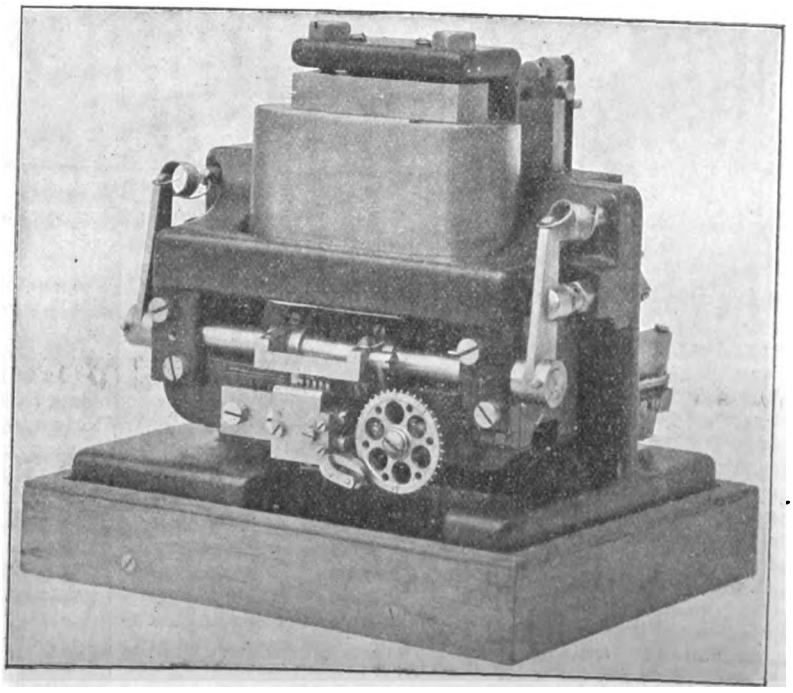

Fig. 2.—Murray Multiplex Receiving Perforator.

words per minute, it may at times overtake the operator. A starting and stopping lever is therefore provided on the automatic transmitter shown at S. This is arranged with a locking mechanism so that the operator can only start or stop the transmitter at the right

Digitized by Google

moment. There is therefore no danger of interrrupting a letter signal in the act of transmission. In this way the operator has complete control over the tape. It is possible to make a much simpler tape transmitter than that shown in Fig. 3 if the perforations in the tape are arranged crossways, but in that case the tape would not be interchangeable on the Murray multiplex and the Murray automatic systems.

Tape transmission involves considerable increase in capital cost compared with direct transmission, and it also involves cost for paper tape, but the saving in line and labour is so great that it far outweighs the increased expenditure.

One disadvantage of tape transmission is that a rapid operator may go on perforating until he is several messages ahead of the transmitter. An inquiry may then come through from the other station, and the operator cannot transmit his answer until the messages already perforated have been transmitted. This may take two or three minutes, and it would delay delivery of a message at the other station. An arrangement has accordingly been designed, by throwing over a switch, to convert the keyboard perforator temporarily into a direct transmitter. The tape transmitter is switched out, and the punching magnet of the perforator becomes a cadence magnet. Five contacts are provided on the perforator to be operated directly by the keys. As soon as the reply is transmitted the switch is thrown over again and tape transmission is resumed. The method of governing the distributor is similar to that employed in the Murray automatic system. It will be seen in Fig. 4 that there is a local battery and a circuit passing through a local relay described as the governing relay. When the two brushes at the two stations reach the two negative contacts on the two distributors the main line relay contact will be opened, and there will be no local action at station B. If now the vibrator at station B is adjusted to run 1 or 2 per cent. faster than the vibrator at station A, then the rotating brush of the distributor at station B will run 1 or 2 per cent. faster than the brush at station A. Hence, when the brush at station A is on the plus contact, so that the main line relay contact at station B is closed, the brush of the distributor at station B will have reached the minus contact. The result will be that the local circuit through the governing relay already referred to will be closed, and consequently the governing relay contact will be momentarily opened. In this way the governing impulse from station A will repeat its retarding influence four times a second on the brush at station B. In this way the two brushes at stations A and B are kept not only at the same speed but also in phase, so that when the brush at station A touches successively contacts 1, 2, 3, 4, 5, the brush at station B will also be touching successively contacts 1, 2, 3, 4, 5, on the distributor at station B. Any permutation of signals sent out from the keyboard at station A will therefore be exactly reproduced in the five setting magnets of the printer at station B.

Fig. 5 is a sectional side elevation of the printer, which is driven by a small $\frac{1}{16}$ H.P. motor. As the printer will print correctly as long as it is driven faster than the distributor, there is no need for synchronism between the printer and distributor, the former being arranged to run anywhere about 20 to 30 per cent. faster than the latter. The Blickensderfer typewriter is employed, and the message forms are fed in automatically from a roll made up in a rather unusual way. The message forms are perforated along each side like a cinematograph film, so as to gear on to sprocket pins on each end of the typewriter platen. The message forms, in addition to being perforated along the edges, are lightly pasted together so as to overlap and at the same time form a continuous band, which is wound into a coil. The perforations ensure positive column and page-feed, and the overlap of the message forms renders it very easy to pull the messages apart after they are printed.

One argument used against page-printing by those who have been trained up in the use of tape printers like the Hughes and Baudot is that, as every correction and inquiry involves the use of a message form, there is great waste of message forms. Actual observation during the practical trial by the British Post Office showed that the loss from this source did not exceed 5 per cent. of the message forms used, and even this small loss could be halved by a little care and foresight. Also the writer has designed an arrangement by which inquiries and corrections (R Q's) can be obtained directly printed on a tape, thereby avoiding any waste of message forms, and also avoiding delay.

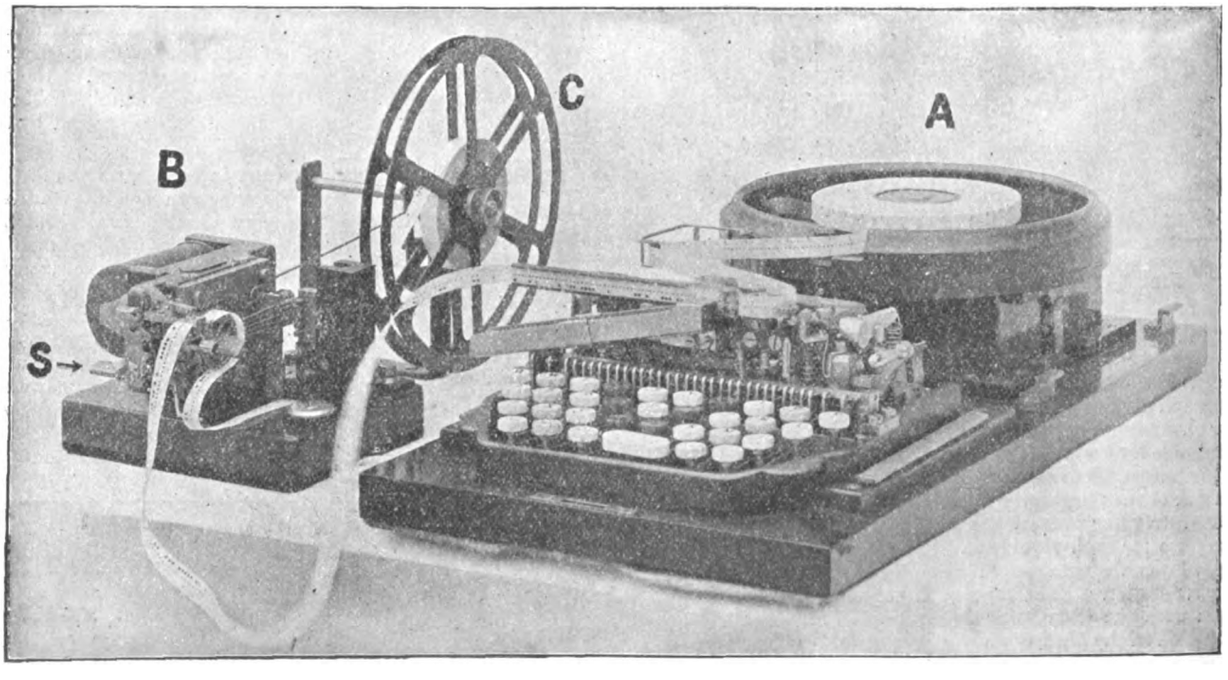

Fig. 3.—Tape Transmission Equipment of Murray Multiplex.

An important point to be noted about this multiplex printer is that the five setting magnets have very little work to do. They have merely to perform a slight releasing operation. Consequently they can be successfully operated by a very small contact on the distributor. The value of this lies in cases where a considerable number of transmissions (four to six) may be required. Under such conditions the contacts on the distributors are necessarily very small.

Receiving Perforator.—With a multiplex printing telegraph system it is a comparatively easy matter to give three towns, A, B and C, independent and simultaneous communication with each other on one telegraph wire. In the Murray automatic system all the received messages are first recorded at a high speed as perforations in paper tape, and from this perforated tape the messages are afterwards printed automatically. In the Murray multiplex a different kind of receiving perforator (Fig. 2) is provided. It is essentially a Murray keyboard perforator tilted on end and with the keys omitted. In place of the keys there are five small magnets which do the work of the keys—that is to say, they control selectively five small steel rods, which determine the holes to be punched in the paper tape. These five magnets correspond exactly with the five setting magnets of the multiplex printer (*see* Fig. 4). Each of these five setting magnets of the receiving perforator are placed in series with the correspond-

Digitized by Google

ing one of the five setting magnets of the printer. The punching magnet of the receiving perforator is operated by the same impulse as that operating the printing magnet (Fig. 4) of the printer. On the printer there is provided a switch to throw the receiving perforator into or out of action by means of a signal from the distant station. If the sending operator at the distant station A has a message which

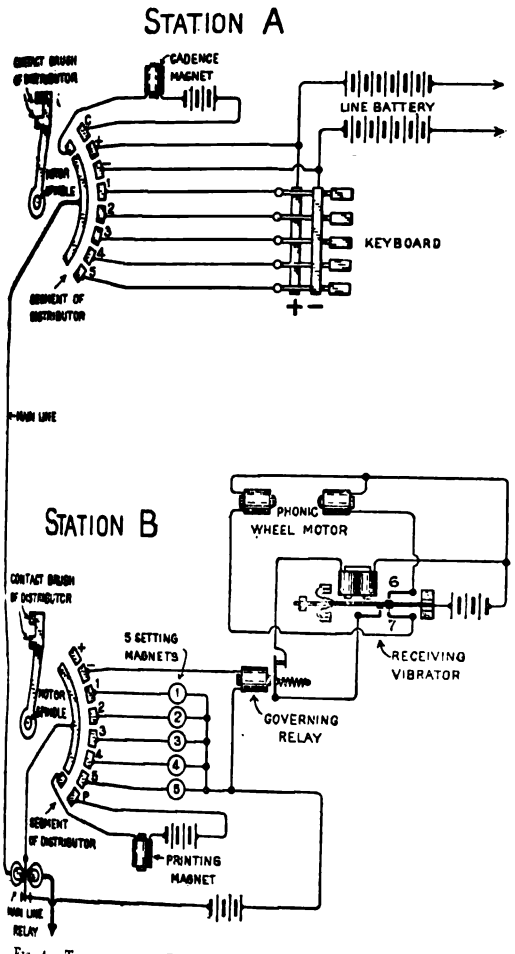

FIG. 4.—THEORETICAL DIAGRAM OF MURRAY MULTIPLEX.

requires to be transmitted at station B to, say, station F, he transmits a special signal which throws over the switch in the printer at station B. This puts the receiving perforator in action. The message is then recorded as perforations in tape by the receiving perforator at the same time as it is being printed in page form by the printer. At the end of every message the page signal, in addition to turning up a fresh telegraph form, automatically cuts out the receiving perforator.

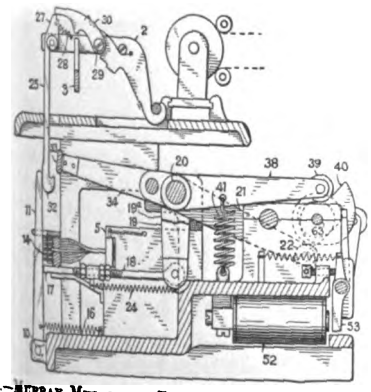

FIG. 5.—MURRAY MULTIPLEX PRINTER: SECTIONAL ELEVATION.

Consequently only messages requiring retransmission are perforated, and the sending operator has control over this operation at the distant station. As there is a printed message produced at the same time as the perforated tape, a glance at the printed message will show whether it has been correctly received. If it has been received correctly, then it can be automatically retransmitted to its destination by means of the perforated tape. If the message has not been accurately received, it can be corrected and sent in the ordinary way by manual instead of automatic retransmission.

Results with Murray Multiplex.—It is too early yet to say positively what results can be obtained with the new Murray multiplex system. A complete installation has only recently been completed for the British Post Office and is now being installed between London and Manchester. Prior to this, an experimental set, giving one transmission only, was made by the British Post Office, and tried for about six months between London and Birmingham. The results were surprisingly good. The sending operators were two girls without previous experience on typewriter keyboards, and yet within one month they were each punching from 40 to 45 messages an hour. After about three months' practice each of these two girls succeeded in perforating 100 messages in one hour. On several days during busy hours the average exceeded 100 messages an hour.

DISCUSSION.

Major W. A. J. O'MEARA congratulated the author upon having turned his attention to the Baudot principle. Many inventors of printing telegraphs had an idea that the usual telegraphic message was about 1,000 words long, and gave their attention to dealing with such long messages; but Mr. Murray was fortunate in having had some experience of British Post Office telegraph work, having been on the engineering staff for some considerable time. His invention, therefore, was based upon experience and was of a very practical kind. He (the speaker) entirely agreed that the telephone in the future would be a feature of the telegraph system. The problem of the telegraphs had, of course, to be very carefully considered, since in the future they might come to a state of affairs when there were only long-distance telegraphs. In that case all they would have to take care of would be the line, and to formulate a system which would make the best use of that "line time" in connection with messages the majority of which averaged 18 words. Mr. Murray was showing them how they could make better use of the "line time." He (Major O'Meara) personally had an opportunity recently in America of discussing that subject. Some persons thought that the use of a transmitting tape involved waste, but he thought if they considered the matter carefully they might alter their opinions. If a telegraph operator, especially with the page-printing system, made a mistake, one of two things had to be done—either repeat the whole message or make a correction. A correction, however, on the form which went to the public was a mistake, as the public were suspicious, and if they saw a correction they suspected "cooking." In America he had observed that the whole message was rejected if a mistake was made. That entailed considerable waste of the "line time." Personally, he was inclined to think that in connection with all high-speed systems the tape was the proper thing, especially if the tape could be inspected before it was put through the transmitter. In that way he thought they would have the greatest use made of their "line time."

Mr. F. HIGGINS (Exchange Telegraph Co.), in a communication sent to the meeting, said he could not endorse the references made in the Paper to the difficulty in distinguishing pounds, shillings and pence from fractions. He showed an example of a telegraph tape where the shilling mark was used for dividing pounds, shillings and pence, and the horizontal bar in fractions. As to the advantage of the telephone as a feeder to the telegraph, his Company had to handle at times as many as 500 telephone messages, and to distribute them to as many receivers. The transmission of ordinary messages and the transmission of news were, he said, absolutely different. There were many apparatus brought forward for securing high speed of working, but owing to the necessity for accuracy his Company preferred to sacrifice a little speed in order to obtain accuracy. The apparatus they had in use worked without skilled attention.

Mr. G. F. MANSBRIDGE (Postal Telegraph Factory, Holloway) agreed with Mr. Murray in regard to the telephone assisting the telegraph. He, however, gave a word of warning; the telephone could never do a great deal in assisting the telegraph because the principle on which messages were sent was fundamentally different in each case. Telegraph messages were tripped out letter by letter, but telephone messages were sent in chunks. That difficulty alone would prevent the telephone becoming a large feeder to the telegraph. In ordinary commercial messages many words and phrases would be found which offered difficulties comparable with ordinary code words. The telephone might be useful for ordinary messages, but could not be of great use, in his opinion, for commercial messages.

Mr. F. RYAN (Eastern Telegraph Co.) said, in regard to the use of the keyboard perforators, that the cable company with which he was connected experienced some difficulty in working these instruments, and were now trying to modify them so as to function with 12 keys instead of 52.

Mr. S. EVERSHED thought Mr. Murray had given an extremely clear exposition of a complicated matter both in his first Paper some five years ago and in the present case. In telegraphy the counting of the number of words seemed to be a nightmare. He suggested that the sender might be compelled, without knowing it, to count the message and also add up the cost of the telegram. That could be done by the use of squared paper telegraph forms, one letter to go in each square or compartment, and the cost to be printed at intervals of, say, six letters along each line of compartments.

Digitized by Google

Mr. A. J. STUBBS (G.P.O.) said it was interesting to note that Mr. Murray had arranged a device for temporarily changing a perforator into a transmitter. That was done some two or three years ago by Baudot, of Paris. In regard to the latest instrument of Mr. Murray for receiving simultaneously upon the printed page and the perforated tape, he anticipated that that would be an extremely useful device under the circumstances described by the author. Supplementing Major O'Meara's remarks in regard to slip versus page printing, he believed Mr. Murray rather anticipated Major O'Meara's comments in regard to the faults made by the operator in preparing the slip. No device, however, could anticipate faults introduced by the line, and however carefully the slip might be prepared by printing devices, there would always be errors introduced by defects on the line, and it was that which made page printing so liable to come out too faulty for transmission to the public. With slip printing all the faults could easily be cut out by the operator when gumming up the slip.

Mr. WALTER JUDD did not suppose that any such apparatus as that of Mr. Murray would be adopted for long-distance cable work; but in any system adopted the International alphabet must be retained. The cable companies regarded that point as very important, as in the case of the punching or printing apparatus breaking down they wanted to have the power of reverting to the old well-tried recorder system. It would be awkward to have two different alphabets in use. He was much interested with that part of Mr. Murray's paper where the traffic aspect of the system was dealt with. There were very great difficulties in such matters, because in a page-printing telegraph it was impossible conveniently to correct mutilations and errors. In the tape system there was the trouble of getting the wet copy, but mutilations and errors could be cut out. Then as to the tape that had to be perforated at the receiving end ready for further transmission, many difficulties cropped up there from the traffic point of view. He was hoping, however, that before very long they would have a machine that would be suitable for cable work. One had been designed many years ago by Mr. S. G. Brown that worked up to a certain degree of perfection. He thought now they had got a machine of their own design that would come into use for cable working. The mechanical difficulties were far less than the traffic difficulties.

Mr. J. HUME BELL did not think the advantages to be obtained by the use of keyboard perforators would come up to expectations until they had an improvement in the handwriting of the general public. He was sorry Mr. Murray had stuck to page printing in preference to printing on tape, because it was responsible for many of the difficulties which Mr. Murray referred to, and involved considerable alterations to present practice in dealing promptly with telegrams in large offices. He agreed that the introduction of printing telegraphs would reduce the number of errors, and stated that records showed the number of errors per 100 messages to be as follows: Morse slip 0·011, Morse sounder 0·009, Hughes printer 0·004.

Mr. W. NOBLE said that Major O'Meara had referred to the fact that the author was able to deal with the subject better because of his practical experience in the British Post Office. He had always thought that it would have been in the interests of the department had Mr. Murray spent six months in the telegraph gallery seeing the operators at work immediately he took service in the Post Office. The author would then have foreseen and avoided many of the difficulties which he had experienced. Reference was made in the Paper to the Hughes tape printer which was used for inland work in France and other Continental countries, and also for telegraph traffic between Gt. Britain and the Continent. The British Post Office was now extending the use of the Hughes as well as the Baudot for inland work, and the use of the latter would be increased as more apparatus became available. The result was entirely satisfactory. Some few years ago the Hughes duplex system came into use here for inland work, and at the present time 12 circuits were equipped with that apparatus. He did not know whether it was the introduction of Mr. Murray's apparatus into the British Post Office that caused the latter to return to its old love—the Wheatstone—but, in any case, trials had been made with the automatic Wheatstone with highly satisfactory results. The present day scheme of Wheatstone working with keyboard perforators and the pasting of the Morse slip was very economical. Some 70 to 75 per cent. of messages had to be retransmitted, and for this work the Morse slip pasted on forms was equally reliable, and more economical than the printing apparatus. Furthermore, the Wheatstone was largely used by the Post Office for news, and there was always spare apparatus available in case of breakdown, whereas with the printing telegraph duplicate sets would always have to be available. He had a doubt whether Mr. Murray would get continuously out of the new multiplex machine 40 words per minute. The Baudot gave an average of 30 words per minute, and he doubted if Mr. Murray's instrument would go above that. As to the use of the telephone facilitating telegraph transmission in the future by merchants sending telegrams direct to the telegraph operator, as outlined by Mr. Murray, he did not think that was likely to happen. After all, the sending of telegrams over the telephone was a very slow process, and in London the Post Office handled many thousands of messages per day, sent through pneumatic tubes in large batches. With a larger number of messages coming over the telephone the aggregate delay would be much greater than at the present time, and many telephone circuits and many operators would be required to cope with the traffic.

Mr. DONALD MURRAY, in reply, said there was much conservatism on the part of the public and also of the Government. In all matters of the kind under discussion, however, there was a very old and highly esteemed gentleman who influenced all parties—namely, Anno Domini; and he thought that Anno Domini was on his side. He would reserve any further reply for the "Journal."

REINFORCED CONCRETE ELECTRIC LAMP POLES.*

BY L. C. SABIN.

Recent improvements in progress at St. Mary's Falls Canal, Michigan, necessitated replacing several electric light poles and adding others. The poles in use were made of timber and had to be renewed quite frequently because of decay just above the ground surface. It was decided to build an experimental pole of concrete, and this proved so satisfactory as to warrant the construction of 40 poles of the same type.

The poles are 11 in. square at the base, and 6 in. at the top, with the corners chamfered by inserting in the corners of the mould triangular strips 1in. on a side. The reinforcement consists of one ⅞ in. square, twisted bar, 34 ft. long, in each corner, extending from about a foot above the base to the top, and two similar bars ½ in. square, 25ft. long, in each side, extending to within 9 ft. of the top. The bars were tied together at intervals of 4 ft., with two turns of No. 6 soft steel wire, bent to a square, within which the rods were placed and secured at proper spacing by winding with stove wire.

In the centre of each pole is placed a standard black gas pipe, 1¼ in. diameter, in two lengths of 15 ft., to lead the wires from the cut-out box, near the base, to the top crook.

The wires are brought from the main conduits through 2 in. galvanised duct to the concrete base in which the pole is set, and up along the outside of the pole to the cut-out box, located about a foot above the base. The connection from the lamp to the top crook or goose neck is made through a high-tension insulator and outlet bell.

The poles were moulded in a horizontal position. For finishing the sides the film of neat cement was removed by rubbing with a flat piece of sandstone and water, leaving a "sand" finish. Later, carborundum blocks were found well adapted to this purpose. Some of the poles first made were painted with a neat cement grout tinted with yellow ochre, but it was later decided that the natural gray of the concrete was preferable. The poles are set in a block of mass concrete 3 ft. square by about 4 ft. deep.

The material and labour required per pole and the cost are given by the author for the following wages per eight-hour day: Foreman, $3; carpenters, $2·25 to $2.75; cement finisher, $2.25; common labour, $2. The entire cost of forms is included in the cost of 42 poles, although much of the material is good for further use. The total cost per pole may be summarised as follows:—

	£	s.
Pole as moulded	7	6
Transportation to site	0	14
Erection, including base	4	16
Wire, cut-out, &c.	4	1
Wiring and fitting up pole	1	1
Total cost	£17	18

Considering the fact that the life of a wooden pole is quite limited and that such poles must be painted annually, at a cost of about 4s., there seems to be no question that the concrete pole is more economical, especially where the wires are placed underground. As proof of this the following cost for wooden poles is given:—

	£	s.
Cost of trimmed pole	5	2
Transportation to site	0	12
Erection, including base	4	8
Wiring, &c.	5	2
Total	£15	4

The strength of the concrete pole was determined by a test of a pole moulded for the purpose, without the central pipe, top casting, and steps, but in other respects the same as the regular poles. Five feet at the butt of the pole rested on a mass of masonry, about 3 ft. above the ground, to which it was firmly secured by two pairs of fox-wedge bolts, one pair being placed 12 in. and the other 42 in. from the end of the pole. Near the top, and 29 ft. 7 in. from the edge of the masonry, was hung a platform which could be loaded with cast-iron weights. The pole developed a moment of resistance of 528,000 in.-lb. before showing any signs of failure. The yield point appears to have been reached when the bending moment was 628,000 in.-lb. The maximum moment developed was 800,000 in.-lb. At this point the measured deflection was 27·2 in., but as the loading platform touched the ground this measurement is somewhat too low.

After the load was removed the deflection decreased to 12¾ in. the small tension cracks along the pole in the upper side, extending about half the depth, remaining plainly visible.

ELECTRIFICATION OF THE LONDON, BRIGHTON & SOUTH COAST RAILWAY.

With the taking over of the tramways by the London County ...ncil and the electrification thereof, the Brighton Railway Com. ...an began to feel the very serious competition of the cars, and in ...0, having obtained Parliamentary powers, instructed their con...ring electrical engineer, Mr. Philip Dawson, M.Inst.C.E., to report ... the whole question ...the electrification of ...ur railways. As a ...sult of this report Mr. ...wson was instructed ... prepare specifica... which were issued ... 1905, and tenders ...ived. After careful ...sideration, the con...ct was awarded early ... 1906 to the Allge... Elektricitäts ...sellschaft, of Berlin, ...ose tender was con...dered by the railway ...mpany to be the ...ost favourable from ...l points of view. The ...ntract let was for ...hat is known as the ...uth London line, ...hich connects the two ...ntres of London ...idge and Victoria, ...d passes through ...st Brixton, Denmark ...ill and Peckham ...ye.

The decision as to ...hat system to adopt ...as not arrived at until ...fter the most careful ...amination and consideration of all that had been done hitherto, ...nd of the special problems involved in the electrification of the ...righton Railway. One of the important points which could not be overlooked was that the very heavy traffic already existing between London Bridge and Brighton rendered it likely that if electrification proved a success on the suburban system, it might afterwards have to be extended as far as Brighton. It was for this reason that the single-phase system was adopted, and results have fully justified the installation of this system.

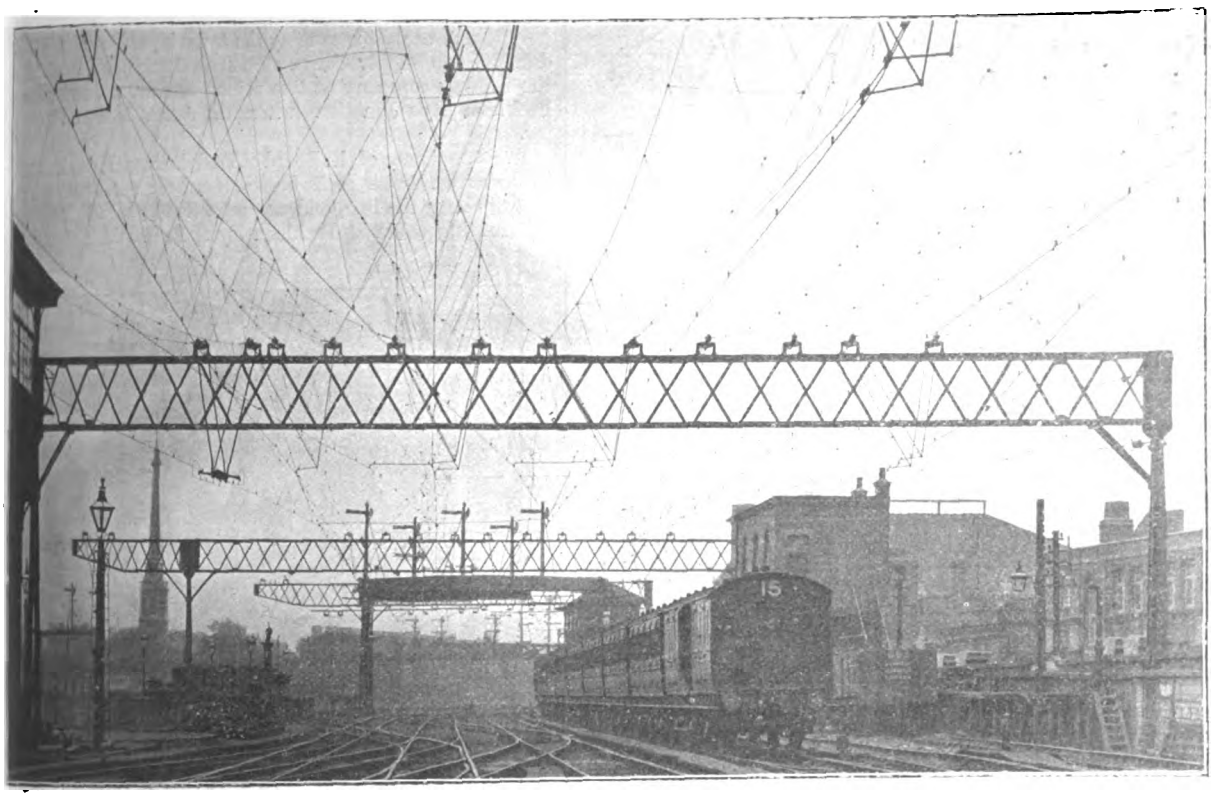

FIG. 1.—LONDON BRIDGE YARD, LOOKING FROM STATION.

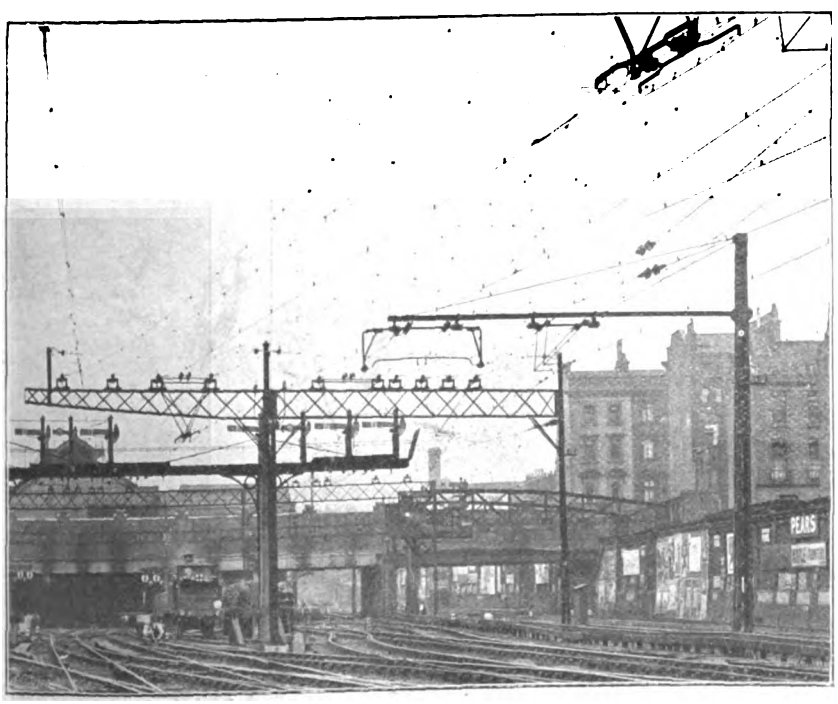

FIG. 2.—VICTORIA YARD, SHOWING LOW BRIDGE ENTERING VICTORIA STATION.

In laying out the scheme for the first electrification the fact was carefully considered that the success of this portion of the line would lead to the electrification of the whole suburban system. With this end in view the plans were so drawn up that the first portion to be electrified should form an integral part of the whole electrification, if and when completed.

Experimental trains were run on the South London line early in 1909, the full electric service being taken up in December of the same year. The length of the route is 8·7 miles, and this is equivalent to 20½ miles of electrified single line. The average distance between stations is 4,590 ft., whilst the shortest distance between any two stations is 1,386 ft. The route is very tortuous. But notwithstanding the difficulties, the journey (including 20-second stops at each station) is easily accomplished in 25 minutes. Five platforms are electrically equipped at Victoria, whilst there are six platforms equipped at London Bridge.

The success of the first experiment has been so great that in May

Digitized by Google

of last year the directors decided to extend the electrification, the new sections being those portions between Peckham Rye and West Norwood, Victoria, West Norwood, the Crystal Palace and Selhurst;

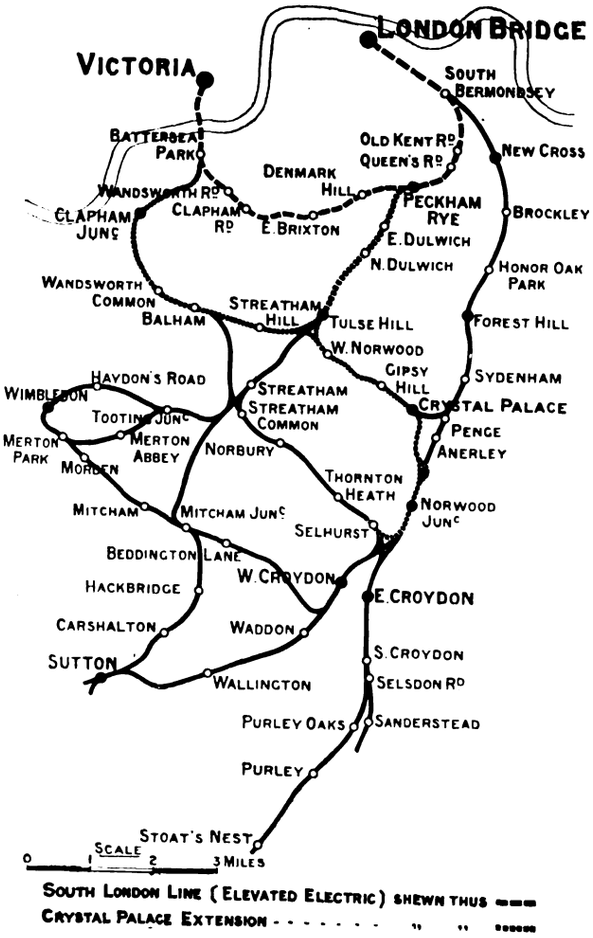

FIG. 3.—DIAGRAM MAP OF SUBURBAN SYSTEM, LONDON BRIGHTON & SOUTH COAST RAILWAY.

thus bringing up the total amount of single track electrified to 62 miles. Fig. 3 is a map of the whole suburban system.

The rolling stock on the South London line consists of 16 motor coaches, each equipped with four motors which will give an output of 115 H.P. for one hour and 57 H.P. continuously, without the temperature rise of any part exceeding 75°C. In the middle of the day the trains are made up of two coaches, one motor and one trailer, whilst in the morning and the evening two such trains are run coupled together.

The rolling stock for the extensions consists of 30 motor coaches, each equipped with four motors capable of giving 175 H.P. for one hour, and 100 H.P. continuously, during the hours of lighter traffic. One of these motor coaches will deal with two trailer coaches, thus making up a three-car train, whilst in the morning and afternoon six-car trains will be run. Side doors in the compartments have been used for all the stock, as the end door type would not have enabled the carriages to be sufficiently quickly filled and emptied at the termini. The experience of this form of stock has been entirely satisfactory.

Electric energy for running the trains is purchased from the London Electric Supply Corpn. station at Deptford, and is delivered to the railway company at two points—namely, at Queen's-road and Peckham Rye Junction—where the current is metered and paid for.

In consequence of the Board of Trade limiting the drop in potential in the return circuit, series booster transformers are located at various points along the line, and are connected by special cables to the distributing cabin at Peckham Rye. Besides this, a so-called distributing cable is run the whole length of the electrified line, the inner being in parallel with the overhead conductors and connected to them at each switch cabin, whilst the outer is bonded to the rails. Besides these cables there are a series of telephone wires run along the line connecting the various switch cabins.

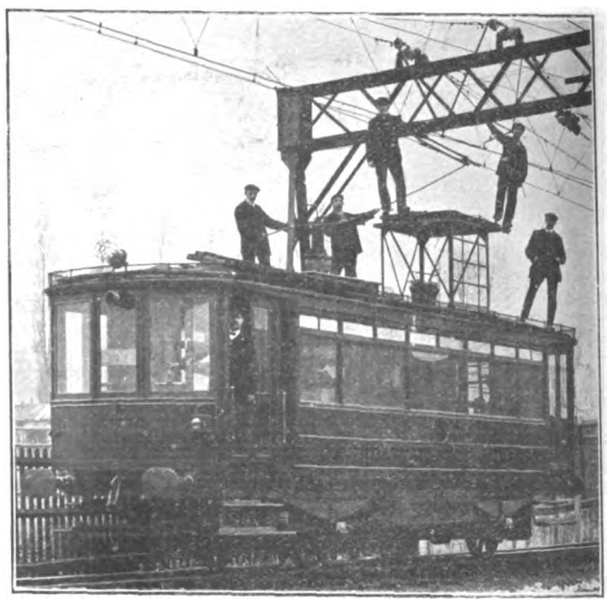

FIG. 5.—PETROL-ELECTRIC REPAIR COACH.

FIG. 4.—INTERIOR OF PECKHAM RYE REPAIR SHOPS.

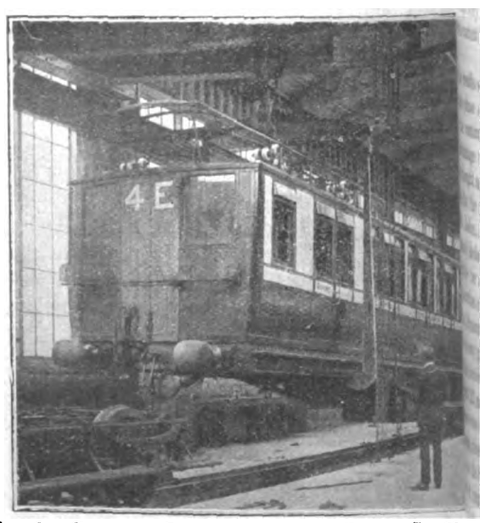

FIG. 6.—CARRIAGE LIFTING DEVICE IN REPAIR SHOPS.

Great care has been devoted to the design of the overhead work and the result of 18 months' practical working has been entirely satisfactory. The construction adopted is of the double catenary type, the contact wire being supported from the catenary every 10 ft. The contact wire itself is of copper, round in section, but with

Digitized by Google

two sharp grooves on either side, in which the clips supporting the wire are fixed. The whole of the insulation is of porcelain, a special form of insulator being used, which has given every satisfaction. The choice of this particular size and type of insulator was the result of a large number of carefully conducted and practical tests extending over nearly 12 months. No tightening device is used for the conductor wires, and experience has shown that, at any rate in the case of the English climate, such devices are entirely unnecessary.

None of the high-tension circuits are accessible when alive. The bow collectors are of very special design, as they have to operate at varying heights, there being a difference of 6 ft. between the highest and lowest working positions. The bows are fitted with aluminium strips in which are deep grooves filled with grease. This arrangement has given excellent results. All the wear is practically taken by the strips, the wear on the copper contact lines, after nearly 18 months running, being inappreciable.

For the South London line, car sheds and repair shops were erected near Peckham Rye, and it is here that electric trains are inspected, and that overhauling and maintenance is carried out. The shop is supplied with electric cranes and capstans, which greatly facilitate operations.

Fears have been expressed in the past that any overhead line will greatly interfere with the sight of signals, but experience has not shown this to be the case.

The normal line pressure on the contact wire is 6,700 volts and the frequency 25 cycles per second. The energy consumption has been most satisfactory, and compares more than favourably with what has been done on continuous current lines. The energy consumption per ton-mile for the first eight months of 1910 as metered at Queen's Road was 75·4 watt-hours per ton-mile. In this figure nothing is included for weight of passengers, and no mileage is allowed for empty running or shunting, whilst all the energy used in the repair shops and all leakages are included. It must also be borne in mind that all trains are stopping trains, and that, therefore, the line works under unfavourable conditions when compared with other railways which have a certain number of "non-stop" trains.

The acceleration obtained is also satisfactory, being equal to that obtained on most of the continuous-current railways in Great Britain. The average acceleration as the speed rises from 0 to 30 miles an hour is at the rate of one mile per hour per second.

The total weight of a four-car train empty is 150 tons, and of this the electrical equipment, including all cables for lighting, lighting fixtures, motor compressor, and all electric gear, boosters, &c., amounts to 15 tons in the case of the South London line rolling stock. In the case of the new Crystal Palace extensions, however, the weight of a three-car train is 102 tons, and the weight of the same equipment on the same basis as above is 19 tons. The energy consumption on the trains during trial running on the South London line was 69·1 watt-hours per ton-mile measured on the train.

In consequence of the adoption of the single-phase system the transmission losses between the distributing station at Peckham Rye and the trains have been kept very low. All the losses from the distributing station where the current is paid for, up to the trains, being about 8 per cent.

understand that the results so far obtained have fully justified that the single-phase system is cheaper to instal and to work than the continuous-current system, and it possesses additional advantage that it is very suitable for extension as far as may be thought necessary by the railway company. Interesting to note that the most eminent railway authorities Prussian, Bavarian, Baden, Austrian, Swiss and Swedish State have unanimously declared in favour of the single-phase as the only suitable for main line railway electrification, the suburban, interurban or long-distance work.

Signals maintenance, 18 months' experience shows that there is to expect this to be any greater with single-phase than with current, and that notwithstanding the fact that the average during the first 12 months by every one of the motor (including all spares) was over 58,000 miles.

Regards financial results, these have been equally satisfactory; the railway company lost, on the South London line alone, in a very few years, in consequence of tramway competition, over 5,008,000 passengers. Although very little alteration was made to the fares the whole of the traffic was practically recovered within the first 12 months, and the number of passengers is increasing daily. It may be mentioned that the whole of the work was designed and carried out under the supervision of the railway company's consulting electrical engineer. In Figs. 1, 2, 4, 5 and 6 we illustrate various portions of the electrified track, and also the repair shop at Peckham Rye.

The contractors for the whole equipment of the South London electrification, excluding coaches, were the Allgemeine Elektricitäts Gesellschaft, of Berlin, the coaches being constructed by the Metropolitan Amalgamated Carriage & Waggon Co., of Saltley, Birmingham. The sub-contractors for the whole of the overhead line work, including feeders, switch cabins, &c., were Messrs. R. W. Blackwell & Co., who, in their turn, sub-contracted with the British Thomson-Houston Co. for the switchgear, and with Messrs. Siemens Bros. and Messrs. Johnson & Phillips for the cables required.

The cranes and capstans were supplied by Messrs. Stothert & Pitt. The contractors for the extensions now nearing completion are Messrs. the Allgemeine Elektricitäts Gesellschaft, of Berlin, for the electrical equipment of the trains; the Metropolitan Amalgamated Carriage & Waggon Co., for the motor coaches and part of the trailing stock (the remaining part of the trailing stock being constructed by the Brighton Company at their own works at Lancing); and for the overhead work, feeders and distributing system, Messrs. R. W. Blackwell & Co.

The repair shops and carriage sheds at Peckham Rye, as well as the switch cabin buildings and the new carriage sheds for the electrical stock at Norwood Junction, were designed and carried out under the supervision of Mr. Charles F. Morgan, the chief engineer of the Brighton Company.

THE NEW IRONCLAD-EXIDE BATTERY FOR ELECTRIC VEHICLES.*

BY L. H. FLANDERS.

In the development of the lead sulphuric acid battery for vehicle service the problem has been to secure high capacity per unit of weight consistent with durability. To meet this need the "Exide" battery was introduced in 1900, and since that time has been a most widely used battery for automobile propulsion. The author refers to the main features of this battery, and explains that if the positive active material could be prevented from being detached from the supporting grid and still be retained in a healthy and operative condition, the plates would have a very much longer life.

The manufacturers have now developed a battery with a positive plate which has even greater capacity per unit weight than the Exide positive, and which is so constructed that the loss of its active material is reduced to a minimum. On account of its remarkable durability, the new battery is called the Ironclad-Exide.

The positive plate of this new battery consists of an alloy framework, comprising top and bottom bars integrally connected by conducting cores of the same material. Surrounding these cores are the uniform pencils of active material, protected by horizontally laminated rubber tubes. Each tube is formed with two narrow vertical ribs diametrically opposite each other which take the place of the spacing ribs on the ordinary wood separator and, at the same time, give added strength and durability to the tube.

The negative plate is of the same general construction as the regular Exide negative, but it has been made somewhat thicker in order to withstand the longer life of the Ironclad positive. The outside negative plates are thinner than the inside negatives. A feature of the Ironclad-Exide battery is the flexible pillar strap connector. It consists of alloy terminals cast around lead-plated copper strips, which give great conductivity and flexibility,

The Ironclad-Exide elements are interchangeable with Exide elements. To give a concrete example: a 24-cell nine MV. Exide battery, weighing approximately 720 lb. complete, including trays, and rated at 28 amperes for four hours, will receive nine MV. Ironclad elements. It then will weigh approximately 740 lb., with an initial rating of 28 amperes for 4½ hours, or 30⅔ amperes for four hours. The rating is conservative, yet, when compared with the Exide positive, which is rated at 7 amperes for four hours, there is an increase of 12·5 per cent. in initial rating.

Using the four-hour rating of the MV Exide, at the same rate of discharge current per positive plate (that is, 7 amperes), the Ironclad-Exide battery, weighing but little more, will start with 4½ hours—*i.e.*, an initial increase of 12·5 per cent. in ampere-hours output. It will reach a capacity of from 4¾ to 5 hours within about 25 discharges, and from 5½ to 6 hours within about 200 discharges. It will then retain a capacity above its rating for practically its entire life, in some cases reaching over 1,000 cycles before dropping below its 4½-hour rating. The initial capacity at the 4½-hour rate would be about 8 watt-hours per pound of complete battery, increasing to a probable capacity of over 11 watt-hours per pound of complete battery.

For the present, the "Ironclad-Exide" batteries are being assembled and charged only by the manufacturer. Formerly, great stress was laid upon frequent and systematic cleaning; but the "Ironclad-Exide" will rarely, if ever, require cleaning, since its active material is so firmly held in place.

THE NEW WIRING RULES.

In a rapidly developing industry, such as electric engineering, rules determining the methods of carrying ou certain work can, at the best of times, be based only on temporary standard to which it is desirable that all wor should at least attain, and they must of necessity be open t criticism if not frequently brought up-to-date. Althoug it is but four years since the fifth edition of the Wiring Rul of the Institution of Electrical Engineers was issued, th need for revision has been felt for some time past. Th Wiring Rules Committee being now a Standing Committe the process of revision has doubtless been much simplifie the Committee being ready at all times to receive suggestion as to any desirable amendments to the Rules. Criticism ha been raised in certain quarters as to the composition this Standing Committee, which includes representatives the Municipal Electrical Association, the Cable Make Association, the Electrical Contractors' Association, and some of the principal Fire Offices. Although the Committe which comprises 15 members, includes a considerable numb of central station engineers—past and present—this, w consider, is by no means a disadvantage, since such enginee should be in a particularly favourable position for becomi

Digitized by Google

acquainted with the weak points of the average wiring installation. A complaint has been raised as to manufacturers being unrepresented on the Committee, although they are particularly affected by any decisions reached; we scarcely think, however, that this complaint is necessary, for the Committee would doubtless pay full regard to any representations that came from such a quarter. That members of the Committee are themselves unaffected by any change in the Wiring Rules is by no means a disadvantage.

On the present occasion, probably the most important change in the Rules is in connection with the current-carrying capacity of conductors. Until recent years, engineers have frequently adopted the 1,000 ampere per square inch rule, which enables the carrying capacity of any conductor to be at once ascertained from its cross sectional area. This "rule of thumb" method, however, has had to be abandoned in view of more careful experiments on insulated cables. As mentioned in the recent report of the National Physical Laboratory, the Electrotechnics Department of the Laboratory have carried out an exhaustive series of tests on the carrying capacity of insulated conductors, and the Table issued with the new Rules is based upon this research. The carrying capacity stated for the various cables allows a temperature rise of 20°F. in the case of rubber-insulated cables, and of 50°F. for paper or fibre insulated cables. On this basis a 1/18 S.W.G. conductor of either type may now be used for currents up to 7·2 amperes (i.e., a current density of 4,000 amperes per square inch), as against 4·2 amperes according to the Rules previously in force. The distinction between rubber insulated and paper and fibre insulated cables is certainly a step in the right direction, and is to be welcomed. In the case of small wires, the current carrying capacity of each type of insulated conductor is identical; but in the larger sizes the difference is very marked, amounting to over 60 per cent. in some cases. The maximum permissible currents with large rubber insulated conductors are less than those set out in the previous Rules, whilst the use of paper or fibre insulated cables allows the latter figures to be considerably exceeded. It must, of course be understood that the current carrying capacities given in the Table are conditional on a certain fall in pressure not being exceeded for lighting circuits. It is interesting to note that this drop in pressure, in lead and return, is not to exceed 2 per cent. of the supply pressure, *plus one volt*. The reason for this increase is not clear, since the use of lamps of higher efficiency has effected a considerable reduction in current.

It is certainly in keeping with recent practice not to stipulate for such a high insulation resistance as was once the case, and except in the case of 1/18, 1/17 and 1/16 S.W.G. conductors less than 2,000 megohms per mile are required for low pressure rubber covered cables, the figure varying from 1,250 megohms in the case of the smallest wires to 600 megohms in cables larger than 0·06 sq. in. For medium pressure cables the figures vary from 4,500 to 2,500 megohms. The pressure test applied to cables also tends to become less severe. Thus, previous to the Rules issued in 1907, a cable had to be bent six times round a cylinder before being subjected for 10 minutes to an alternating pressure of 2,000 volts at 50 cycles. In the fifth edition of the Rules, however, the bending of the cable was omitted, and the duration of the pressure test increased from 10 to 30 minutes. In the new Rules the testing pressure is reduced to 1,000 volts, and no mention is made of alternating current or any frequency. In view of the custom hitherto of specifying alternating current for the majority of pressure tests, the omission of this condition on the present occasion is noteworthy.

In connection with the clause in the 1907 edition of the Rules stating that "all conduit systems must be electrically and mechanically continuous throughout," it is now pointed out that slip sockets do not comply with this rule, some form of screwed or grip joint being necessary. As to earthing of such conduits, the omission of earthing in the case of short lengths "enamelled externally" is not rendered any clearer than in the previous Rules. In commenting four years ago on the Rules, attention was called to this clause; but we notice our suggestions for special attention to bath-room fittings and to earthing wires are dealt with in the new Rules. We are also pleased to see that the Committee have revised the Rule specifying the maximum overload to be carried by fuses before interrupting a circuit. This Rule as it stood might undoubtedly have allowed dangerous overloads in the case of large conductors; and whilst it is still permissible to protect small circuits (up to 10 amperes) by fuses so that the current is only interrupted when it exceeds the normal value by 200 per cent., an overload of 100 per cent. has been fixed for larger circuits.

Concerning other alterations little comment is necessary, except to draw attention to the prominence now given to earthed concentric systems. Although such systems cannot be connected to public supply mains except by means of double-wound transformers, they will probably be more extensively used in future where independent generating plant is installed.

Finally, we are pleased to notice that the Committee have borne in mind the Home Office Regulations for installations in factories and workshops, and these Regulations are reprinted with the Rules, whilst the Rule as to a lampholder not being in metallic connection with the guard or metal work of a portable hand lamp has evidently been taken from the Regulations. This clause, it will be remembered, gave rise to much discussion at the time, but its operation has since been made clear by Mr. RAM in an Official Memorandum.

A History of the Cavendish Laboratory, 1871-1910. (London, 1910: Longmans, Green & Co.) Pp. xii. + 342. 7s. 6d. net.

On December, 22, 1909, Sir J. J. Thomson completed the 25th year of his tenure of the Cavendish Professorship of Experimental Physics in the University of Cambridge. To celebrate this event, his immediate colleagues have published a volume of memoirs by various co-workers and friends dealing with the work of the Cavendish Laboratory from its institution. The result has been the production of a book of great interest to all modern physicists, and one that will undoubtedly be of great assistance to future scientific historians.

Digitized by Google

The book naturally divides into three periods, corresponding to the three holders of the Cavendish Professorship, viz. :—James Clerk Maxwell (Cavendish Professor, 1871-1879), Lord Rayleigh (Cavendish Professor, 1879-1884), and Sir J. J. Thomson (Cavendish Professor, 1884), truly an illustrious triumvirate!

The story of the Maxwell period is told by Prof. Schuster in an extremely interesting chapter. He himself was the first research student in Cambridge. It is hard to realise that 44 years ago there was only one laboratory in the world (that of Jamin at the Sorbonne) where systematic instruction in practical physics was being given, and that Maxwell had practically no precedents to help him in arranging or equipping a laboratory. Thanks to the generosity of the seventh Duke of Devonshire, the laboratory was built and equipped so handsomely that after a few years Maxwell was able to state that the equipment comprised the whole of the "instruments required by the present state of science"—a happy condition which has never since been attained.

The question of the accuracy of electrical measurements soon engaged Maxwell's attention, and the classical research on the accuracy of Ohm's law was carried out under his direction, as was also the work of the Committee of the British Association on Electrical Standards.

In Prof. Schuster's words, "Maxwell's personality dominated the Laboratory and united those who worked in it. . . . It was the seriousness with which he discussed all ideas put before him by his students that, from the beginning, gave the laboratory its atmosphere of pure and unselfish research."

Dr. Glazebrook treats of Lord Rayleigh's tenure of the chair, a period of extreme activity. The practical classes were organised by Glazebrook and Shaw, and for some years their text-book of "Practical Physics" was the book used in the Cavendish, and in almost every other English-speaking physical laboratory. In a few concise pages Dr. Glazebrook shows the growth of the system of absolute electrical units, and one realises what a great debt the electrical industry owes to the few able men who put the electrical units on a sound scientific basis.

The period of the last 25 years has been subdivided amongst four writers, Newall, 1885-1894; Rutherford, 1895-1898; C. T. R. Wilson, 1899-1902; and N. R. Campbell, 1903-1909; with an introductory survey by Sir J. J. Thomson himself. All these chapters are of intense interest, telling of the growth of a great research organisation, concentrated (with a few brilliant exceptions) on the study of the electric discharge, and from that to the relation between electricity and matter.

Prof. Thomson in his survey, dwells on the social side of the laboratory, and it is undoubtedly the feeling of comradeship that impresses all who come into contact with the workers in the Cavendish Laboratory. Prof. Bumstead, of Yale University, in a letter to the editors, emphasises this fact:—"But your social life struck me as much richer and fuller than ours; really we seem too busy to enjoy each other's society, and yet we do not get so much done as you. I don't understand it altogether: a laboratory in this country in which nobody ever began work before 10 a.m. or worked later than 6 in the evening would serve as a terrible example of sloth and indolence. I do not see how you get so much work done and yet have time to live so pleasantly and unhurriedly. We Americans have never discovered that great secret. . . . Another thing which struck me as paradoxically fine was the relation between the professor and his students. The great admiration and reliance with which 'J. J.' was regarded by everybody was unquestionable; yet in matters of detail there was no subserviency. I saw a good many men, while I was there, following their own courses, and I remember well the frank tone prevailing at the meetings of the Cavendish Society, where the professor's theories or experiments were not spared in the general criticism."

Prof. Thomson, in his survey, is generous to all who have helped him in his work, and the many friends of the late Prof. Cassie will be grateful to Prof. Thomson for the story he tells of his high-mindedness and self-sacrifice.

Prof. Wilberforce writes on the development of the teaching in the laboratory, and gives some amusing examples of the "howlers" made by early students in the laboratory. Warm praise is given by several of the writers to the admirable teaching and research work of G. F. C. Searle.

Enough has been said to indicate what an extremely interesting book this history is, not only by reason of the scientific work therein discussed, but also from the point of view of the varied personalities taking part in it. All who read it will hope that Sir J. J. Thomson may be long spared to carry on his work. R. S. WHIPPLE.

Electric Circuit Problems in Mines and Factories. By ELLIS H. CRAPPER, B.Eng. (London: The Chichester Press) Pp. 159. 3s. 6d. net.

Attention has frequently been drawn in official reports and elsewhere to the fact that amongst those who are placed in charge of electrical plants in mines and collieries are many whose electrical knowledge is not so advanced as should be the case in view of the great responsibilities which naturally fall to them. Given an electrical system properly designed and installed, in charge of a thoroughly competent engineer, there is no method of lighting, no form of power so safe in mining work as electric. Mr. Crapper's work on "Electric Circuit Problems" has been prepared with the object of providing readily available information regarding the elementary principles, laws, and methods of testing electric circuits in mines. That such a work as this was needed is beyond dispute, and even those who consider that their knowledge is amply sufficient for all practical purposes will find much of value and interest in its pages.

The author deals with the fundamental principles of the electric circuit, and not only shows how the various problems which arise in practical work may be solved, the sizes of conductors calculated, and losses determined, but also points out how circuits should be tested, and how any faults which exist therein may be located. The opening chapter deals with the units of measurement, following which are chapters on insulation and circuit testing. A number of pages are devoted to cables and methods of testing same; and the characteristic features of both continuous and alternating-current circuits are dealt with exhaustively. The space allotted to each subject has been carefully proportioned to its relative importance, and the book can be confidently recommended to all engineers in charge of, or employed in connection with large electrical plants. G. B. B.

THE DRIVING OF WINDING ENGINES BY INDUCTION MOTORS.*

BY H. J. S. HEATHER.

Summary.—The author discusses the use of induction motors for driving winding engines, and shows that, although not so efficient in power consumption, his suggested arrangement is superior to the Ward-Leonard system as regards simplicity and safety. Emergency braking in case of failure of supply is obtained by exciting the stator from a source of continuous current.

For hoisting and winding work on a polyphase system of electric supply the direct application of the driving power of the induction motor has not hitherto been so general as its indirect application through the medium of continuous-current plant operated on the Ward-Leonard control system, with or without the Ilgner flywheel. The principal causes which have prevented the adoption of the less costly direct induction motor drive have been, first, the losses arising from the waste of energy in the rheostatic control, which losses are avoided in the Ward-Leonard system; and, secondly, the difficulties arising from the nature of the relations between torque, speed, and resistance in the secondary circuit of the induction motor.

Some tests carried out by the author on a three-phase winder for the Village Main Reef Gold Mining Co. in 1906 convinced him that the first of these two objections was more or less groundless; and some figures he obtained as to relation between the foot-pounds of useful work done in lifting rock in the shaft, and the electrical input compared on practically equal terms with the most satis-

* Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

factory results that he has seen given for a converter system. It is, therefore, with the second objection only that he proposes to deal.

In the first place he describes the Ward-Leonard control, showing its extreme simplicity and that it has the very great advantage of being regenerative in its action. With induction motors the only simple method of speed control, that of inserting resistance into the secondary circuit, is comparable when lifting, so far as wastefulness is concerned, with the rheostatic control of continuous-current motors. In each case a definite torque at a speed between full speed and zero can only be secured by using the full power that would correspond to it at full speed. Both in simplicity of operation and wastefulness, therefore, the induction motor and the rheostatically controlled continuous-current motor are on a level when lifting at speeds below full speed.

When lowering loads at speeds below full speed the continuous-current motor can be operated with rheostatic control in two ways. The more economical is to cut off the supply of current to the motor

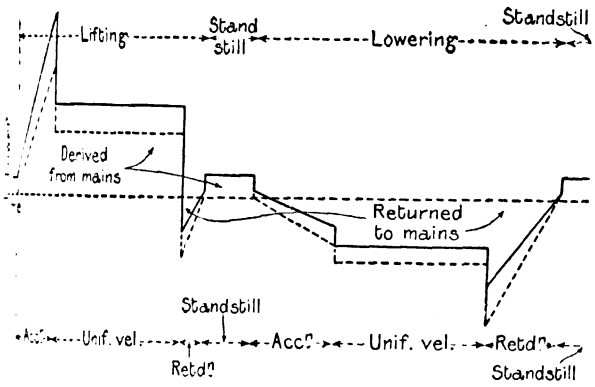

FIG. 1.

armature and allow the motor to operate as a generator, absorbing in the resistance the whole of the power generated, the power derived from the mains being only that required for excitation. The complication, however, of switching off the mains from the motor armature and short-circuiting it through the resistance is introduced, and it becomes necessary to reverse both these movements to bring the motor absolutely and steadily to rest by electrical means. The alternative method, more wasteful in power, but simpler in operation, is to leave the motor connected to the mains, to take from them the current corresponding to the desired motor torque, and to absorb in the resistance both the power represented by this current and that produced by the hoisting motor, now operating as a generator driven by the descending load. The action of the induction motor when lowering loads may be considered as almost exactly similar to the latter of the above described actions of the rheostatically controlled continuous-current motor. It is equally simple and equally wasteful.

Equally simple methods of winding engine motor control being therefore available, it follows that the direct induction motor drive must usually have by far the best over-all simplicity, as practically all heavy transmission work is done on the three-phase system, and consequently, whenever continuous-current motors are employed, some form of converter is a necessary additional complication.

In order to show that the foregoing remarks on the simplicity of induction motor control are justifiable, the author gives a few explanatory notes and diagrams to illustrate the properties of the induction motor and the requirements of winding operations. The circumstances assumed are the simplest possible—in fact, they are simpler than those that occur in practice, for although it is sometimes feasible to make the ropes balanced, this is very often not the case; acceleration and retardation are never uniform, and the problem is generally complicated to some extent by the use of conical or cylindro-conical drums, or flat rope reels. The modifications thus introduced, although they frequently involve reversing moments, are merely matters of detail. It has been shown, however, that if mechanical brakes are supposed not to be relied upon, and all control has to be effected electrically, the operation of a winding engine demands the possibility of getting any torque in either direction at any speed in either direction, subject, of course, to the limitations imposed by a maximum torque and a maximum allowable rope speed. The fulfilment of these requirements is equally possible by either the Ward-Leonard or the direct-induction motor drive.

Referring in practical work the most usual form of Ward-Leonard power-time diagram, which is also the most unfavourable to the induction motor drive, is that shown in the first half of Fig. 1, where the power given into and coming out of the winding drums is given by the dotted lines. In order to ascertain the power taken from the mains, the efficiency has to be taken into account. The result is, of course, to increase considerably the portion of the diagram above the zero line, representing power taken, and to decrease the portion below the zero line representing power returned. The power consumption diagram for a pair of trips, one up and the other down, will be somewhat similar to that shown in Fig. 1.

To get the corresponding power consumption diagram for the direct-driving induction motor, the action of the motor under reverse current and at speeds below full speed must be kept in mind. The power consumption diagram will, in consequence, be derived from the torque-time diagram, but the reversal of the direction of the torque does not mean the return of power to the mains. The power derived from the mains corresponding to any torque is now independent of the speed, and even of the direction in which that torque is exerted, and the power taken from the mains is determined by dividing, by the fraction representing the efficiency of the motor at the instantaneous speed and ampere load, the power that would be put into the winding drums at full speed, and adding thereto, for the lowering trip, the power that would be given out by the winding drums at full speed multiplied by the corresponding fractions for efficiency. The full line in Fig. 2 may be taken as showing the power taken from the mains during a lifting and a lowering trip separated by an interval, the dotted line being the power put into and taken out of the drums. It must not be forgotten that, both in Fig. 1 and in Fig. 2, the whole of the operations are supposed to be carried out electrically, no mechanical brakes at all being used. This accounts for the high power consumption of the induction motor during the period of standstill. There will be very little chance that the energy taken by the induction motor for such a pair of trips, the one raising and the other lowering a load, will be less than that taken by the Ward-Leonard arrangement to effect the same operation. If, however, the number of times that loads have to be lowered is small, and if the length of trip is long, and the interval between trips long, and mechanical brakes are allowed to hold the load at rest, it is quite possible for the direct-driving induction motor by its economy on the uniform speed portion of the trip, and when standing still, to do more than make up for its extravagance in power when starting and stopping.

It should be noted that the long duration of the acceleration peak when lifting is an important disadvantage when the supply is obtained from a small power station. Another point worthy of notice is the large amount of energy that the controlling resistance of the induction motor has to be capable of taking up. In Fig. 2 it would be represented by the area enclosed between the full line, which shows the power being taken from the mains and the dotted line which shows that being put into and taken out of the winding drums. This area would be reduced only by the losses in the winding motor whether operating as motor or generator. During the lowering

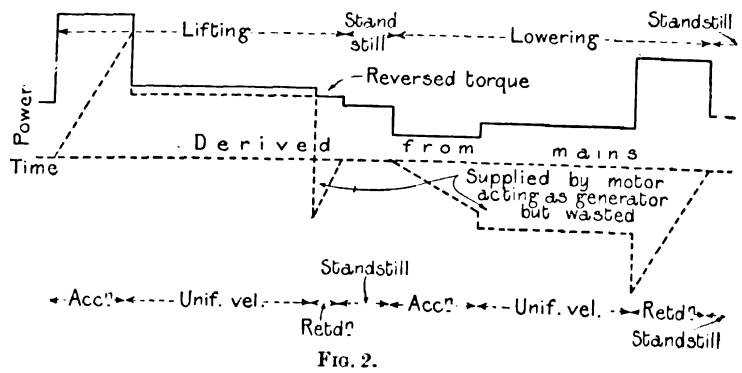

FIG. 2.

trip this energy will approach twice the value of that which the motor is capable of taking in. The dissipation of this large amount of energy in the case of a big winder need, however, present no difficulty in practice to the mechanical engineer, who is accustomed to deal with a similar problem on a similar scale when he runs his steam engines on condensers.

There are, of course, several ways of avoiding this loss in lowering. For instance, it may be permissible to allow a slightly higher speed when lowering, so that the induction motor running above synchronous speed may act as a generator returning power to the mains, or a similar result may be attained at a lower speed by using a two-speed motor. Both these methods entail complications in the manipulation of the controlling lever, and the writer prefers to pin his faith to the simpler process of using reverse current and to face the losses.

Apart from the question of economy, the chief argument that is brought forward by the advocates of the Ward-Leonard system

Digitized by Google

against the direct induction motor drive is that it is difficult for the driver to tell at any time whether he has to increase or decrease the resistance in the secondary circuit in order, say, to increase the torque. There is, however, an extremely simple way of getting an absolutely certain guide to this. It is to use an ammeter as a torque indicator in exactly the same way as is done in the Ward-Leonard system. The author explains from the torque-slip curves why this simple method can be applied. To all possible torque-speed curves there is only one torque-ampere curve. This curve shows that the amperes go on increasing from the point of zero to que, when the ampeaes are the no-load current of the machine, to the point of maximum torque, and that even after this is reached, though the torque begins to diminish, the amperes continue to increase, reaching their maximum value (which is in the neighbourhood of $\sqrt{2}$ times the value at maximum torque) only when the slip is infinite, that is, when an infinite backward speed is reached, by which time the torque has again become zero. It can, therefore, be absolutely

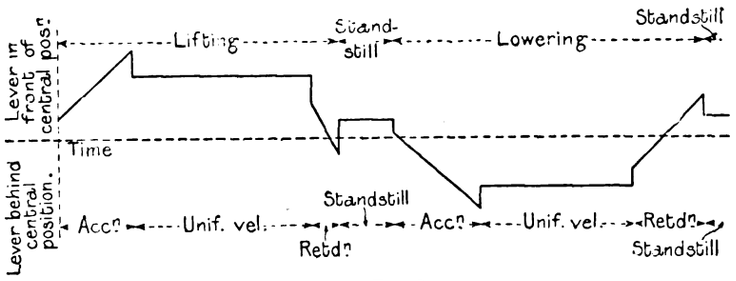

Fig. 3.

ensured that the full-line portions of the torque-slip curves are always being worked to, by making certain that the full-line portion of the torque-ampere curve is being worked to; and this simply means that the amperes must not be allowed to exceed a certain maximum value, which can readily be fixed once for all for any individual motor. In practice, a reasonable margin would be allowed to cover inequalities in the voltage of supply, &c., and the driver would be instructed never to allow the amperes to exceed the lower value so decided upon.

So far as driving in one direction is concerned, therefore, the simplicity of the control of the direct-driving induction motor is brought exactly level with that of the continuous-current motor of the Ward-Leonard system. The fact that in the latter case the torque-ampere curve is more nearly a straight line than in the former does not affect the matter in the least, as it is in both cases an indication, not of current but of torque, that is really needed, and there is no necessity for the scale to be uniform. But the polarised ammeter ordinarily used in the Ward-Leonard control goes further than merely to show the approximate value of the torque; it indicates also the direction, and this is undoubtedly useful. A similar result can be arrived at very simply and at very small cost for the induction motor drive. With this drive a reversal of the direction of the torque can only be obtained by reversing the direction of rotation of the field in the stator. This can be, and usually is, done by the movement of the same lever that inserts or cuts out resistance in the rotor circuit; and it is easy to make this lever, at the same time that it reverses the stator field, put into circuit a second ammeter coil which deflects the common needle in a direction opposite to that which the first ammeter coil gives it.

It will be seen that the guide afforded to the driver of the winding engine with the direct induction motor drive is, under the author's arrangements, almost exactly similar to that which the driver of a Ward-Leonard set has to rely on. The similarity, however, extends further than this: the necessary movements of the control lever are almost precisely similar in kind, though not in extent. If the double trip, once lifting and once lowering, be considered, the movements of the lever necessary to secure this with the Ward-Leonard may be plotted as shown in Fig. 3. The corresponding diagram for the induction motor drive is shown in Fig. 4, which corresponds to the power diagram of Fig. 2. It must not be forgotten that throughout these diagrams acceleration and retardation have been assumed to be uniform, and consequently they begin and end suddenly. In practice, all angles in the diagrams, and particularly the peaks, would be rounded off. A further modification of the last diagram, owing to the fact that all resistance is usually cut out when lifting at uniform velocity with an induction motor would result in levelling down any peaks that are shown as rising above the line of lifting at uniform velocity.

In comparing Fig. 4 with Fig. 3 there are two points to notice. The first is that exactly similar movements, so far as direction is concerned, are required under both systems at every stage of both lifting and lowering. It cannot be contended that the direct induction motor drive introduces any complication. The second point is that when lowering a load with the induction motor drive a forward position of the lever is required throughout. In this respect the duties of the driver of the induction motor agree quite closely with those for raising and lowering with steam and without using mechanical brakes, and this might properly be used as an argument in favour of the direct-driving induction motor where the problem is one of conversion from steam to electric driving. The author, however, does not attachany importance to this, as, in his experience, drivers accustomed to steam and put on to electric driving have, in a few days, invariably preferred the electric control, whether on the Ward-Leonard or the direct-driving induction motor system.

It should be pointed out that the cycle of operations depicted in the diagrams above is not the cycle that usually has to be carried out in practice. Ordinarily there is a succession of trips, all lifting loads, first with the one drum and then with the other. Such a succession of trips may be followed by a series of lowering trips.

As to an emergency safety arrangement in case of a failure of supply from the three-phase mains, ordinarily if this were to happen with the induction motor drive, the driver would be rendered helpless except for his mechanical brakes. Except for the small additional safeguard supplied by the inertia of the converter set, the same thing is true with the Ward-Leonard system, if, as is usually the case, the source of supply is three-phase. Of course, if the Ilgner flywheel is added the large flywheel inertia is a solid protection.

It was pointed out some years ago that electric braking could easily be obtained on an induction motor by exciting either stator or rotor with continuous current. The possibilities of this proposal do not, however, appear to have been recognised at that time, and nothing much appears to have been done with it owing to the failure to discover any satisfactory method of control. The suggestions thrown out by the author supply such a method. The source of continuous-current supply can be made of such a voltage that the primary field strength produced by the current it sends through the stator will be equal to that produced by the alternating current corresponding to the maximum torque. Even if applied to the stator this will only require quite a low voltage, as the opposition to the current flowing in an induction motor stator comes mainly from the inductance and not from the resistance of the circuit. The effect of the time constant, after the failure of supply, is not so great as to form an insuperable obstacle. It is possible with a moderate continuous voltage to get, within a fraction of a second, a stationary field from the stator equivalent to that required when the rotor current corresponds to maximum torque. The effect of this stationary field is to convert the induction motor into a synchronous generator capable of converting at any particular *speed* the same mechanical torque that it could deal with as a synchronous generator at the same speed above synchronism.

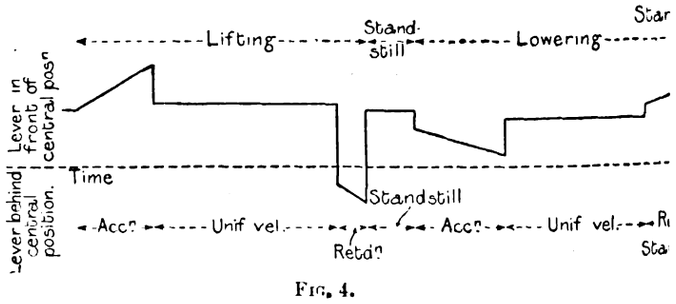

Fig. 4.

If arrangements are made so that the opening of the main circuit breaker (owing to failure of supply) automatically closes the stator circuit on to a suitable source of continuous current, and the ammeter which acts under normal circumstances as a torque indicator to the driver, is placed in the rotor circuit, the driver has, under emergency circumstances, exactly the same reliable guide as he uses for employing as a brake when working on the limiting torque principle before described. He can use for braking a torque equal to the normal full-load torque of the motor down to a speed which is the same fraction of synchronous speed as the normal slip—that is to say, down to a speed that is perhaps 5 per cent. of the synchronous speed. It is obvious that this speed is so low that any sort of mechanical brake can then safely be applied in order to complete the process of bringing a descending load to rest.

This continuous-current excitation can also be applied to the induction motor of the converter set of a Ward-Leonard system, and would certainly, as an emergency arrangement, increase its safety

(*Continued on page* 179.)

Digitized by Google

when lowering loads. Its application to this case is not, however, so simple as its use on the direct-driving induction motor, for it would be necessary for the driver, under the emergency conditions, to pay attention to the reading of an ammeter on which he did not have to depend for normal running.

In this brief outline of a scheme for using the induction motor for driving winding engines, the author hopes that he has gone into sufficient detail to show that, although his proposals are more expensive in power consumption where much lowering has to be done, they embody arrangements which are superior to those of the Ward-Leonard system as regards simplicity and safety. Inasmuch as the cost for the simple induction motor is lower than that for a Ward-Leonard set, he considers that he can at least claim that where cheap power is obtainable from a large power plant and capital outlay is a consideration, he has made out a case for the induction motor.

CORRESPONDENCE.

ACCUMULATORS AND PORTABLE PHOTOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of January 13th Mr. A. P. Trotter comes warmly to the defence of the practice, which in a previous letter I have by implication condemned, of trusting to the constancy of the voltage of an accumulator in making measurements with a portable photometer. Mr. Trotter finds it surprising that anyone with practical experience should suggest the necessity of using electrical measuring instruments as an adjunct to street photometry, and supports his contention that such instruments are superfluous by showing discharge curves of a certain accumulator.

With the data which he presents I can find no fault. The relevant fact, which no tests are required to bring out, is that the voltage of accumulators does change with time, and that the voltage of a freshly charged accumulator drops off quite rapidly during the early period of discharge so that its constancy cannot be relied upon to within 1 per cent. for more than a few minutes. Of course, I understand that an experienced man would not trust to the constancy of this portion of the discharge curve in photometric work. Unfortunately, however, not all those who use portable photometers are experienced in the handling of storage cells. Therefore, some of them at least are likely to fall into serious error on account of this peculiarity. The small change which goes on continuously in the voltage of the accumulator is also something which, in view of the sensitiveness of the candle-power of a lamp to change with current, cannot be neglected if photometric measurements are to be made with due regard for the precision which is attainable at the present day.

At the time when Mr. Trotter, in connection with Sir William Preece, was carrying out his most valuable pioneer work in street photometry, photometric apparatus and portable electrical measuring instruments had not reached their present state of perfection, and in particular the primary standards of photometry were in a deplorable condition, as far as accuracy was concerned. Under these circumstances, the practice which Mr. Trotter adopted of setting his photometer against his lamp at the voltage of his accumulator, and trusting for the same to the constancy of that voltage, was probably the best practice; and the results which were obtained were not appreciably affected by the errors introduced through the decrease in accumulator voltage. At the present time, however, the science of photometry has been raised to a different scale of accuracy. The primary standard, through incandescent lamps, has been fixed to within less than ½ per cent.; the portable electrical measuring instruments have been improved to such a point that they very nearly meet all the requirements of precision for photometric work; the photometers themselves have been refined and improved in reliability and sensitiveness. Therefore, errors which were negligible under previous conditions have become important under present conditions and cannot be neglected by anyone who wishes to do the highest grade of work.

I would call attention to another difficulty in connection with the method which Mr. Trotter so vigorously advocates. He evidently would close the circuit through his photometer lamp only for the few seconds required to make a reading, thereby conserving his storage battery's charge. This is a practice which our experiments at the Electrical Testing Laboratories have shown to be incompatible with the best results. In miniature battery lamps, such as are used in portable photometers, the filament is very short and the percentage of heat lost by conduction through the leading-in wires is relatively very large. These leading-in wires, being of copper, with a high specific heat, are capable of absorbing considerable heat from the filament, and it requires a quite appreciable time for the filament to transmit enough heat to the leading-in wires so that the whole lamp comes into a state of thermal equilibrium. During this time the average temperature, and consequently the candle-power of the filament, is changing. Such a lamp with a given current may have, at the instant the switch is closed, 10 per cent. higher candle-power than it has a minute later. Evidently photometrical measurements should not be made until the lamp has come to a stable condition, which may not be reached until a minute or two after the switch has been closed. It would evidently be impracticable to wait two minutes before making each setting; consequently the lamp must be left burning all the time that photometric measurements are being actively made, and the rate of decrease of battery voltage shown by Mr. Trotter would no longer apply.

It may be objected that such refinements are not required, or even desirable, in street photometry. I do not believe that this is so. We have entered upon a period in which the portable photometer is being used as a most important means of obtaining data bearing on the problems of illuminating engineering. Many illuminating engineers have equipped themselves with portable photometers and are industriously making and publishing measurements bearing on the very practical subject with which they have to deal. It is of very great importance that the data so collected shall be comparable in absolute values. This means that the photometers should be standardised against nothing but reliable standards and that the methods which are employed in their use should be such that the results are not subject to any systematic error which can be eliminated. To use the method which Mr. Trotter advocates, and to obtain therewith results that are at all comparable with those which are readily obtained when the electrical quantities are controlled by instruments, requires that the photometer should be checked at very frequent intervals against a reliable standard of light, in order that the change produced by the falling of the storage battery voltage may be taken account of or compensated for. Even then, the photometrist when using his photometer in outside work must trust implicitly to the constancy of his storage battery voltage and has nothing to assure him that he is not in blissful ignorance of changes which may be taking place, due perhaps, as Mr. Trotter suggests, to bad lamp sockets or faulty switches. Practically speaking, each experimenter working by this method must be equipped with a reference standard of light and must be thoroughly familiar with the use of the same.

If, on the other hand, a reliable ammeter is connected in the circuit with the photometer lamp, and the photometer is standardised at a definite lamp current, the photometrist is justified in feeling the very greatest confidence that no appreciable change will take place for quite a considerable period of time, provided, of course, that his photometer lamp has been properly seasoned before being put to use. The result is that checks against the photometric standard are not conditioned by the user's ignorance of the state of his battery voltage and are not required at anything like as frequent intervals as in the other method, since the candle-power of a seasoned lamp is a much more stable thing than the voltage of an accumulator.

The *reductio ad absurdum* of the no-instrument method has come to my attention in a pamphlet issued by the makers and sellers of the same photometer as called forth my first letter. In this pamphlet it is stated in substance that though a photometric bench in the laboratory is desirable for calibrating the

Digitized by Google

instrument, "results which are amply accurate for practical purposes can be secured" by setting up a standard candle 1 ft. away from the test plate, waiting until a cup of molten wax has been formed and until the wick has an inclined position, and then carrying out a calibration of the instrument against this standard. When we realise that standard candles, used with the greatest care and strictly in accordance with the Parliamentary specifications, often give variations of 5 to 10 per cent., we are tempted to ask what the ideals as to accuracy of the writer of this pamphlet are. Certain it is that a recommendation of this kind will cause careful engineers to view any data obtained with the instrument in question with suspicion. It seems a pity, too, for the photometer itself, as I understand it, should be capable of yielding very good results when used by a proper method. That such a slip-shod method should be promulgated and recommended is, in view of the present state of the art, rather discouraging.

Mr. Trotter does not claim that the use of a proper electrical instrument invalidates in any way the photometrical measurements. He evidently objects to it as unnecessary and even sophomoric. My contention is that, to meet modern requirements as to accuracy and reliability, some electrical measuring device is practically indispensable in serious portable photometer work, and that it is impossible not to regard measurements made without these adjuncts as in general of an inferior order of reliability.

Mr. Trotter's long years of splendid service in maintaining the standards of the Board of Trade, a service which is known and appreciated in this country as well as in England, is a sufficient guarantee of his personal appreciation of accuracy in scientific and engineering work. I believe that he needs only to be convinced that the use of electrical measuring instruments in photometrical work tends toward an increased and not superfluous accuracy, to cause him to withdraw his opposition to this practice.—I am, &c.,

CLAYTON H. SHARP.

We have submitted Mr. Sharp's letter to Mr. Trotter, from whom we have received the following reply :—

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I am in agreement with Mr. Clayton H. Sharp that the practice of photometry has been raised in precision and that an accuracy of ½ per cent. is possible under laboratory conditions. I agree, too, that high accuracy is possible under such conditions with portable photometers. But I do not consider that for street work, and other applications of portable photometers for industrial purposes, time, trouble, skill or money need be expended in securing higher accuracy than a variation of 3 per cent. from the mean of a number of measurements. One reason is that the quantity to be measured, whether illumination due to electric, gas, or daylight, is liable to vary, and another reason is that it is better in street work, &c., to obtain a number of readings of tolerable accuracy than a few readings of high precision.—I am, &c.,

London, May 9. A. P. TROTTER.

[We regret that we are compelled to hold over some correspondence.—ED. *E.*]

CONFERENCE ON THE EDUCATION AND TRAINING OF ENGINEERS.

We are asked to state that a conference on the education and training of engineers will be held at the Institution of Civil Engineers on June 28th and 29th, the Council being of opinion that the present is a desirable time to consider the methods of preparation to be adopted by those who contemplate entering the engineering profession in compliance with conditions laid down in the by-laws for election into the Institution. Questions of detail and of method involved in the realisation of the principles laid down in the report of the Committee on Engineering Education and Training in 1906 will be discussed. The subject-matter of the conference will be divided into three groups : General education, scientific training, and practical training. The subjects which will be introduced for consideration at the conference include : The extent to which mathematical and scientific subjects should share with other subjects of literate education the attention of schoolboys who intend to enter later the engineering profession ; the question of specialised entrance examinations for university or college courses of study in engineering science, with a view to the curricula to be followed, and also of the inclusion in the latter of courses in modern languages ; the relation of practical training to college study, whether, or to what extent, before, sandwiched, or after its conclusion ; the position and uses of engineering laboratories in relation to education at college ; the value of a university degree in engineering science in relation to professional competence ; the requirements of practical training in works, with the necessary complement of scientific study ; practical training in workshops or on works of construction, with special reference to training in the engineer's office ; the relation of engineering employers and colleges from the point of view of the practical training of college students ; workshop training as a preliminary to practical training in other branches of engineering. The subjects referred to will be introduced by means of quite short notes submitted by persons who have been selected on account of their experience or the attention they are known to have given to them. In this way it is hoped to secure very wide attention to the matters which are of general interest and importance. The officers are as follows :—

President : Alexander Siemens (President Inst.C.E.).

Vice-presidents : The Right Hon. Walter Runciman, M.A. (President of the Board of Education), the Right Hon. Lord Pentland (Secretary for Scotland), Sir John Wolfe Barry, K.C.B., LL.D., F.R.S. (Past-president Inst.C.E.), Sir William H. White, K.C.B., D.Sc., LL.D., D.Eng., F.R.S. (Past-president Inst.C.E.). *Honorary Secretary :* James Forrest. *General Secretary :* J. H. T. Tudsbery, D.Sc.

SECTION OF GENERAL EDUCATION.—*Chairman :* Anthony G. Lyster (Vice-president Inst.C.E.). *Vice-chairmen :* B. Hall Blyth, M.A. ; H. A. Miers, M.A., D.Sc., F.R.S. (Principal of the University of London). *Honorary Secretaries :* D. S. Capper, M.A., E. P. Hill.

SECTION OF SCIENTIFIC TRAINING.—*Chairman :* W. C. Unwin, B.Sc., LL.D., F.R.S. (Vice-president Inst.C.E.). *Vice-chairmen :* Sir Alexander B. W. Kennedy, LL.D., D.Eng., F.R.S. (Past-president Inst.C.E.) W. H. Maw, LL.D. *Honorary Secretaries :* J. D. Cormack, B.Sc., Capt H. Riall Sankey.

SECTION OF PRACTICAL TRAINING.—*Chairman :* R. Elliott-Cooper (Vice-president Inst.C.E.). *Vice-chairmen :* E. B. Ellington, James Swinburne, F.R.S., W. B. Worthington, B.Sc. *Honorary Secretaries :* J. W. Jacomb-Hood, E. W. Monkhouse, M.A., Basil Mott.

SOIRÉE OF THE ROYAL SOCIETY.

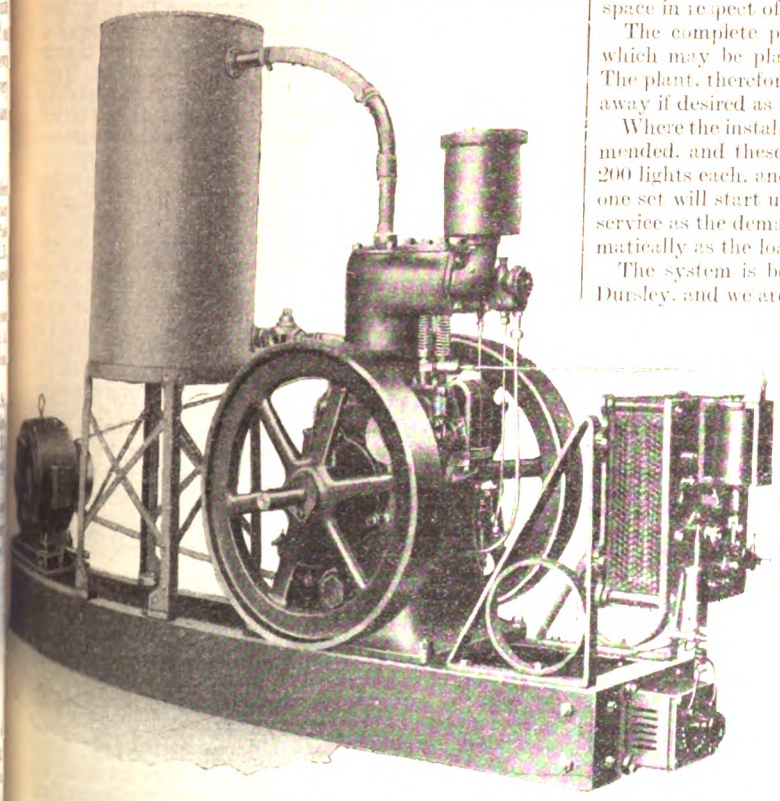
A soirée was held last Wednesday evening when a number o interesting exhibits were shown, although, generally speaking there was not a great deal that was novel from the electrica point of view. Prof. J. A. Fleming, F.R.S., showed Hemsalech' method of rendering visible the oscillatory discharge of a condense the discharge being blown by an air-blast downwards between tw copper knife edges. By this means the effect of varying the fre quency and other effects of that kind can be shown extremely wel It was interesting to notice that on the insertion of iron in the in ductance the frequency was changed to a marked extent, whereas this was not the case when a non-magnetic metal was used as a cor thus demonstrating the fact that the effect was due to magnetism an not to eddy currents. Dr. J. A. Harker, F.R.S., and Mr. C. G. Ede showed an interesting experiment in which two insulated carbon roc were maintained at various high temperatures within a carbon tub Upon connecting a battery to the two carbon rods a considerabl current is found to flow between the latter even with such a lo pressure as 1 volt. As the temperature is raised the current increas and for a given temperature the current increases as the voltage increased until a "saturation current" results. Dr. W. Rosenhai and Mr. S. W. Melsom exhibited a portable potentiometer for ten perature measurements with thermo-couples, the object being t overcome the disadvantage attached to the use of a direct deflectio millivoltmeter for measuring the E.M.F. over wide ranges of ten perature. Prof. W. M. Thornton showed the effect of electrica charges on vegetable and animal cells. It appears that when a electric current is passed through a weak aqueous emulsion of suc cells the animal cells go to the positive pole and the vegetable cells t the negative, thus giving a means of distinguishing such cells in lo

Digitized by Google

forms of life. Other electrical exhibits were shown by Prof. E. Wilson and Mr. S. G. Brown, but these have already been described in THE ELECTRICIAN. Among the non-electrical exhibits mention may be made of Sir William Ramsay's micro-balance, which is capable of registering to about 1/20,000 of a milligramme. It is mostly made of silica, and the method of varying the smallest weights involved consists in altering the apparent weight of the air in a sealed quartz valve by altering the pressure of air in the balance case. Prof. E. G. Coker showed the application of interference colours produced by transparent materials under stress, the materials being used to show the distribution of stress in engineering models, such as beams, parts of engines, &c. There were numerous other interesting exhibits of a non-electrical character, but our space will not permit of a more detailed reference to them.

THE BRUSTON AUTOMATIC LIGHTING SYSTEM.

The introduction of the petrol engine has done much of recent years to simplify the small isolated plant. It makes it possible to place equipments of this nature in the hands of unskilled labourers with a complete assurance of their operating with satisfaction. A system



BRUSTON AUTOMATIC PETROL DYNAMO PLANT.
The solenoid controller on the right starts the dynamo as a motor (with current from the battery) and the plunger of the controller when at the end of its travel lowers the exhaust valve lifter and allows the engine to commence firing.

has now been introduced whereby a practically automatic generating system is obtained. The makers claim that the introduction of this system will reduce the size of the storage batteries and materially decrease the initial cost of installation. The attendant also is only needed to keep the plant clean, lubricate the engine, and to fill up the petrol-supply tanks. When the lights are initially switched on the engine starts up, and when the last light is finally turned off it stops, both the operations being performed automatically. The generating plant is practically standard, in so far as the engine and dynamo are concerned. The only special feature is the switchboard, to which is fixed the various devices which make the plant automatic. A small battery is used in connection with the plant, and this is employed to light up the initial lamps and also to supply energy to the dynamo, which is rotated as a motor for the purpose of starting up the engine. There is a drop of 8 volts over a period of 10 seconds when the engine is being started up. The switching in of the dynamo is effected by a relay which operates after a certain number of lamps have been switched on. The engine, of course, will commence firing when rotating at a certain speed and the voltage of the dynamo will gradually be built up and current will be supplied direct to the lamps. This in time replaces the energy which was taken from the battery to start the engine. As we have said, the engine only starts after a certain number of lamps are switched on, and assuming that this limit is not reached and that the battery is called upon to supply current from the minimum of lamps for a long period, the fact that the battery voltage drops also actuates the relay and causes the plant to start up again and recharge the battery. After the lamps have been switched off and the battery charged up to its normal voltage the plant is automatically stopped. We illustrate the complete plant, to which is attached the solenoid controller for starting the dynamo as a motor. The plunger of the solenoid when at the limit of its travel lowers the exhaust valve lifter and the engine then fires. The magneto is of the oscillating high-tension type and is operated by a "flicker" on the lay shaft. We saw the plant running in London, and it never failed to start up under the conditions specified. The battery is contained in four portable cases similar to those used on motor cars, and occupies a minimum of space.

The makers claim that by the use of their system they save the 40 per cent. loss which generally applies when accumulators are used. The greatly reduced size of the battery effects a material saving on the initial cost of accumulators, and the automatic features of the plant ensure that energy will be forthcoming at any time to cope with whatever demand may be made on the plant. The saving in floor space in respect of the accumulators is also an appreciable item.

The complete plant is mounted upon two parallel steel girders which may be placed on the floor or ground without fixing bolts. The plant, therefore, needs no alignment in erection and can be taken away if desired as it is not a landlord's fixture.

Where the installation amounts to 400 lights, two units are recommended, and these can be either 100 and 300 light units, or two of 200 lights each, and they can be connected up in such a manner that one set will start up on light load and the other will be brought into service as the demand increases. It will be similarly cut down automatically as the load falls off.

The system is being developed by Messrs. R. A. Lister & Co., of Dursley, and we are informed that it has been subjected to a number of trials extending over a long period. The users of the plant speak in enthusiastic terms of its efficiency and satisfactory operation. In a pamphlet which the Company has just issued comparative estimates of the initial cost of the standard and the Bruston system are given. On a 200-light installation there is a saving in the outlay of £64 in favour of the Bruston plant, and it is claimed that if the operating economies are added to this figure the Bruston plant will pay for itself in four years. From the shipment point of view the weight figures are also of interest. For the ordinary accumulator system for a 200-light plant the weight is 35 cwt., for the Bruston system it is 15 cwt.

We understand that the automatic features of this plant place electric lighting for country houses, &c., on a competitive footing with petrol gas, which has come to the front of recent years on account of its simplicity and the fact that no attention is needed. Messrs. Lister have obtained several orders for their Bruston sets in place of petrol gas outfits, and as the plant becomes more widely known a considerable demand is almost certain to arise.

ELECTRICAL TRADES BENEVOLENT INSTITUTION.

We give below a list of further contributions received by the Institution up to Saturday 6th inst. A list of donations and subscriptions received on the occasion of the Festival Dinner was given in our last issue. We may mention that the list is still "open" for further contributions, and we hope to publish still another supplementary list next week.

LEGAL INTELLIGENCE.

National Telephone Co. v. Postmaster-General.

The Railway and Canal Commission (Mr. Justice A. T. Lawrence, the Hon. A. E. Gathorne-Hardy and Sir Jas. Woodhouse) on Tuesday commenced the hearing of the application by the National Telephone Co. against the Postmaster-General in respect of certain terms of the agreement under which the Government take over the undertaking of the Company as from Dec. 31, 1911.

Sir Alfred Cripps, K.C., Mr. Danckwerts, K.C., Mr. Forbes Lankester, K.C., Mr. Edward Morten, K.C., and Mr. H. H. Gaine appeared for applicants; the Attorney-General (Sir Rufus Isaacs), the Solicitor-General (Sir John Simon) and Mr. Bramson represented the Postmaster-General.

In opening the case for the company Sir Alfred Cripps said the agreement between the Government and the Company was that the latter should be taken over on Dec. 31, 1911. The company was to be taken over on what were known as "tramway terms"—*i.e.*, as a going business as to the main part of the undertaking—and its land, plant, buildings, &c., at valuation. The private business of the company was to be taken over on business terms. The mass of the business, however, would be taken over on "tramway" principle, which involved the taking of an inventory, on which about 600 people were engaged, 400 on behalf of the company and 200 on behalf of the Post Office. Under the agreement there was a power reserved to the P.M.-G. to give notice to the company on Jan. 1, 1911, that he should decline to take over certain specified portions of the company's land, plant, buildings and equipment. Notices of that kind had been served on the company in respect of a great part of their property, but the company contended that such notices as had been served were not in accordance with the agreement, and that the P.M.-G. in other particulars misinterpreted the arrangement under which the business was being taken over. It was as to this that the Commissioners were now asked to decide. The capital of the company on Dec. 31 last was £11,483,593, and up to that date the company had actually expended £16,154,566 in the extension of its business. The gross income for the year ending Dec. 31, 1910, was £3,422,425, with a net income of £1,105,572. As an example of the great public service rendered by the company, counsel said that during its existence it had paid no less than £3,457,000 to the Post Office in royalties. In the last year £329,494 was paid in this connection, representing actually 10 per cent. of the company's gross income, exclusive of that derived from the private wire business. The staff of the company numbered 18,000 persons. Sir Alfred then gave a sketch of the history of the invention of the telephone. It was made, he said, by Prof. Graham Bell in 1876; Edison came forward with numerous improvements in the two following years. At that time the Post Office refused to buy the patent, apparently entertaining the notion that the telephone was a mere toy. The patent rights were bought in 1880 by the United Telephone Co., the predecessors of the present company. Towards the end of 1880 a decision was given in the well-known case of the Attorney-General *v.* Edison, the effect of which was that the telephone was a telegraph as regarded ordinary public business as distinct from private business, and came within the Post Office monopoly under the Telegraph Acts. In 1881, the National Telephone Co. was formed and, substantially, had carried on the telephone business of this country since that time. Some years ago the P.M.-G. bought the trunk lines of the company for £459,114. The effect of that was that the control of the trunk lines passed to the Post Office. The question was complicated by the fact that, under the Telegraph Act of 1899 certain municipalities obtained power to establish telephone services. On Nov. 18, 1901, an agreement was entered into between the Postmaster-General and the company, which was again incorporated in an agreement of Feb. 2, 1905. Under these agreements the Postmaster-General had power to give notice to the company at any time not after Jan. 18, 1911, that he might refuse to receive lands, plant, or equipment belonging to the company on the surrender date of Dec. 31, 1911. Under these agreements counsel said the P.M.-G. would also have to pay the company for their private licences running beyond Dec. 31, 1911, and any plant, buildings, &c., in use for that purpose.

Mr. Justice LAWRENCE: The scheme is, then, that you are to come to an end on Dec. 31, 1911?

Sir ALFRED CRIPPS: Yes; that we are then to be taken over by a Government department.

His LORDSHIP: Which takes your place on certain terms with regard to one branch of your business and on other terms on another?

COUNSEL: Yes, as regards certain portions of our own business in which the licences have not expired we ought to get business compensation and we also should get compensation for our private wire business. Continuing, counsel said the P.M.-G. claimed the right to refuse to take over any plant not constructed in accordance with the Government specification, and also any plant that might be found to duplicate plant laid down by the P.O. department, provided that notice was given to the company of the fact before Jan. 1, 1911. The Postmaster-General had given notice that certain lands, plant, and other equipment belonging to the company was so unsuitable, but the company contended that practically the whole of its equipment had been manufactured according to the specifications of the Government. It was also contended, on behalf of the P.M.-G. that the plant, &c., in competitive areas should not be taken over. That, said Counsel, was a contention that could not be maintained. To take, for instance, the immense London area, in which both parties were working. He pointed out what an enormous injustice the contention of the department would inflict upon the company. *Prima facie*, the arrangement was that the department should buy all the company's plant, and it lay upon the Postmaster-General to show cause why he should not do so. It was a duty of the department when it gave its notice of rejection to specify the unsuitable parts of the equipment, and say why they were unsuitable. It was quite insufficient, and wholly out of accord with the agreement between the parties, to give notice that the equipment as a whole at certain particular places was unsuitable. Such a notice gave no information to the company, and the Court would not uphold it. Counsel laid great stress on the wrong interpretation of the word "unsuitable" by the Government. They merely contended that the works of the company were unsuitable if they had enough of their own without them.

The ATTORNEY-GENERAL, interposing, said the Postmaster-General objected to taking over the lines of the company because they were worked on the obsolete magneto system instead of the automatic principle employed in the Government's lines. They were consequently quite "unsuitable" for the purposes of the Post Office Department. The department furthermore objected most strongly to the lines of the company being overhead instead of underground.

Sir ALFRED CRIPPS said that was certainly not in the mind of the Postmaster-General when the notice was given to the company that the Post Office would not be liable to take over certain plant. It was clearly then in the mind of the department that they were to refuse duplicate plant only. And counsel contended duplicate plant to be rejected must be clearly specified. Counsel drew special attention to the deed of Feb., 1906,* under which the P.M.-G. contracted to buy the undertaking of the company. "Subject to the provisions of the agreement that all land, plant and buildings of the company brought into use with the sanction of the P.M.-G. and in use by the company on Dec. 31, 1911, for the purposes of the licensed telephonic business of the company. All licensed telephonic business, any private wire business of the company with any plant, land and buildings used for that purpose. All stores which, on Dec. 31, 1911, are in the company's possession, and which are suitable for use in accordance with the methods of work of the Government. Spare plant of all descriptions in the possession of the company on Dec. 31, 1911." Plant, land and buildings, counsel said, would be held under the agreement to have been brought into use with the sanction of the P.M.-G., if such plant, land and buildings, complied with one of the following conditions, but not otherwise: (*a*) If the plant, land or buildings are not in use (or are in the process of being brought into use) for the purposes of the company's business at the date thereof, or; (*b*) In the case of plant, if such plant is, after the date of this agreement, constructed by the company in accordance with the specification; and rules set forth in the third schedule; (*c*) In the case of land and buildings, if such land and buildings are, after the date of this agreement, acquired or constructed with the consent of the Postmaster-General. Providing that the Postmaster-General, may, by notice in writing given to the company not later than Jan. 1, 1911, object to buy such plant, land or buildings as he considers will not be suitable for the actual requirements of the telephonic service of the Post Office on Dec. 31, 1911.

After dealing with other portions of the agreement treating of the private services of the company, &c., Counsel dealt with the large portion of the equipment of the company which he contended the P.M.-G. should take over unless the department had given specific objection to parts of it before Jan. 1, 1911.

Sir JAMES WOODHOUSE: Do you suggest that the Postmaster-General should have specified each wire to which he objected?

Sir ALFRED CRIPPS repeated that no general objection by the Postmaster-General should avail, but that each particular part of the company's service to which the Government took exception should have been mentioned in the notice to the company. The only object of the notices, so far as he could see, was to give the Government power to refuse to accept certain property, and so take it out of the jurisdiction of that court, by whom it would have otherwise been valued. He wanted all those matters of valuation to come before that tribunal. If the Attorney-General succeeded on the point of those notices, then, of course the matters could never come before the court. He said the decree as to the meaning of the word "suitability" for the use of the Post Office should be left entirely to the court, and should not be decided merely by the notice of the department. It was quite impossible that the notice of rejection should be given in a general form.

The Attorney-General interposed the remark, that, supposing a sufficient specification of some plant were given to which objection was raised, such a notice could not be bad. The Postmaster-General might know that there were certain lines which did not form a complete metallic circuit and which, therefore, he was bound to refuse. Where such a line occurred the Postmaster-General claimed the right to object to it as "unsuitable" under the agreement.

After Mr. DANCKWERTS, K.C., had addressed the Court for the National Company,

The ATTORNEY-GENERAL said the P.M.-G. should not raise any unreasonable objection. The Government really wanted to discover some reasonable way of dealing with what the Court must see was a very difficult matter. He understood the argument of applicants was that the notices given by the Government department was insufficient, and that they were, therefore, void. If that were so, then whether the grounds of their objections were good or bad was an entirely different matter. Of course, all the objections of the Government were not on the ground of "unsuitability." But, if the court came to the conclusion that the notice was sufficient then all they had to do was to decide whether

* This deed is set out on pp. 710 to 714 of "THE ELECTRICIAN Electrical Trades' Directory and Handbook," 1911.

Digitized by Google

the grounds were sufficient. They objected "to accept telephone wires which did not form a complete metallic circuit. They said all overhead wires were unsuitable, and they said, further, that the court could not ask them to specify every foot of overhead cable to which they objected. That would be intolerable. They objected to all overhead cables. They said they ought never to have been used, and that they were quite unsuitable for the requirements of the Post Office business." Furthermore, the paragraph of the pleading which asked that the notices should be declared to be "insufficient and void" excepted from its operation and thereby admitted the validity of other notices or parts of notices in the same form.

Mr. ALFRED CRIPPS, interposing, asked for leave to amend the paragraph in question.

After discussion, and at the suggestion of the Court, it was arranged that the question whether the Postmaster was entitled to reject all duplicate lines as unsuitable for the actual requirements of the telephonic service of the Post Office upon the ground that he is possessed of other efficient plant or buildings suitable for his service in the area in question" should be first argued and decided. It was agreed that this was the most important point at issue, and that if this were once determined, some understanding could be come to with respect to the remainder.

In opening, the ATTORNEY-GENERAL said he read the arrangement as meaning that the Post Office was only to take over plant that would be suitable for its purposes and no other. The company could attribute any hardship to the action of the Post Office. For 30 years they had been carrying on business by the courtesy of that department. What he desired to make clear was, that all along the company knew the position. And as to taking over the wires of the company, he said that the wires of them were on the overhead system with the distributing wires coming down into the buildings they served, while the Postmaster-General held that those wires were quite unsuitable for his purpose, and the question whether they were so or not was for the consideration of the court.

The case had not concluded when we went to press.

Hartlepool Electric Tramways Co. v. Mayor and Corporation of Hartlepool.

Mr. Justice Bray commenced the hearing of this special case on Tuesday.

Mr. Atherley Jones, K.C., and Mr. Eustace Hills were for plaintiffs; Mr. W. Balfour Browne, K.C., and Mr. H. A. McCardie for defendants.

Mr. Jones said it was a special case stated under the Arbitration Act 1908. The arbitration was held in January, 1911, to decide the value of certain tramways at West Hartlepool with a view to purchase by the corporation. The parties were Hartlepool Corporation (the proposed purchasers) and Messrs. Sellon & Ashby, statutory promoters of the line, and the Hartlepool Electric Tramway Co., who were, at the time the line was given, constructing, and became proprietors of the tramway. A point raised by Mr. Balfour Browne (on behalf of the Corporation) was whether the promoters nor the company had any interest in the line at all which entitled them to payment, and he (Mr. Jones) submitted was a curious and novel point.

Mr. Justice BRAY: Did he say who had an interest in it?

Mr. Jones said the position taken up was that no one had any interest except that the tramway was a trespasser in the street, and that any one could sweep it away or indict it as a public nuisance. Messrs. Sellon & Ashby were certainly the proprietors of the line, but the other side said that Messrs. Sellon & Ashby had parted with their interest and had got their money on it, and they were not entitled to the purchase-money. The notice of the purchase was served both on the company and on the promoters, and was served through the intervention of the Board of Trade. The arbitrator (Mr. C. A. Kirby) had valued the tramways at £12,963, and the question for the decision of the Court was whether the arbitrator had jurisdiction to make the award he had done.

Mr. MCCARDIE, for the Corporation, argued that neither the Tramway Co. nor the statutory promoters had any legal right to the money, and that the Corporation paid it they would be surcharged by the Local Government Board auditor.

Mr. JUSTICE BRAY: The proper thing to do is that this arbitrator should make his award, counsel on each side should agree to be without prejudice to their contentions, and then the question ought to be tried by an action for specific performance.

Mr. ATHERLEY JONES, K.C.: The real point is: Is it competent to the original promoters or the company purporting to be assigns (not to whom, as has been pointed out, no assignment has been made although an agreement to assign has been executed and no consent obtained from the Board of Trade?

Mr. JUSTICE BRAY: I cannot (unless you gentlemen agree) try something which is not within the four corners of the special case.

Eventually, both sides agreed to accept, without prejudice, the arbitrator's figure as the value of the undertaking in question, and to try the matter as an action without pleadings before his lordship on June 13.

Glasgow Tramways Assessment.

In the Glasgow Sheriff Court on Monday Sheriff Gardner Millar heard an appeal by Glasgow Tramways Committee against the decision of the City Assessor as to the assessment of the city's tramway system. Appellants maintained that the tramways were railways and should be assessed only on one-fourth of their value as entered in the valuation roll, as, in practice, they claim, that was followed until 1908. The Assessor maintains that the tramways are not railways, and that they are rather like ordinary heritages to be taxed on their full value, except under those statutes which specifically mention them as entitled to the reduced assessment. The sum involved originally amounted to £15,223, but, as adjusted, it now stands at £12,514.

Mr. J. Avon Clyde, K.C., M.P., and Mr. A. Russell appeared for the Tramways Committee, and Mr. F. Cooper, K.C., with Mr. A. Crawford, for the City Assessor.

Mr. CLYDE submitted the schedule of the rates to which the appeal related. The total amount of rates imposed was £27,737. 18s. 2d., and the amount which appellants considered they should not be called upon to pay was £12,514. 8s. 3d., being made up by the differences on 6 out of the 19 rates on the schedule, viz.: Police, sanitary, statute labour, sewage, roads and bridges and parks. The question whether the Tramways Committee were entitled to a reduction depended on whether the expression "railway" in the clauses which provided for restriction of assessable valuation included a tramway. He quoted sec. 36 of the City of Glasgow Act. 1891, in support of his contention. For 39 years nobody ever questioned that the meaning of the statutes was that the tramway was entitled to the restriction as being within the expression "railway." But in 1909 the proposal was made, and it was carried out by the Corporation, of treating the tramway as being not a railway, but as some other form of land and heritage, and therefore liable to be rated on the full value.

The SHERIFF: Is there anything in the question, Why is this exemption given to a railway, and if the reason can be ascertained readily, does it not apply as much to a tramway as to a railway?

Mr. CLYDE said the reason was that the amount of assessable value in railways and the extent of the benefits they received from local government services, such as policing and sanitation, were out of proportion to the benefits which ordinary lands and heritages derived. Stations and depots were rated in the ordinary way, but with regard to the actual lines the benefit derived from the public services were very small. The reasons which led to exemption in the case of railways, canals, or any work which was continuous were applicable to those sort of railways which were laid down on the streets.

Mr. COOPER, K.C., said that practice could not interpret a recent Act of Parliament, and if the rating authority of Glasgow for a number of years had chosen not to exercise their powers to the full that could not be a bar to them doing so now, provided the statutes under which they operated entitled them to a larger claim than they had hitherto made. When they valued a railway they valued a heritable subject—the land that the railway owned and occupied for its purposes. In valuing a tramway they did not get at the value of the land, because it had not got any land. What they did get was the value of an undertaking which had no land, but which, because it rested upon the soil and had certain qualities, was treated as a heritable subject. A tramway would not fall within the section of the 1891 Act. The words there used did not suit the peculiar qualities of a tramway, which were very distinguishable from those of a railway. Up to 1891 there had been no fewer than four previous Acts obtained by Glasgow in which tramways as well as railways were allowed assessment upon one-fourth of valuation. If the tramways were to get a certain reduction on their assessments, the committee must be able to put their finger on the section of the statute which mentioned them.

His Lordship reserved judgment.

London Electrobus Litigation.

On Thursday last week Mr. Justice Neville had before him the action of the Re-Organisation Control Synd. (Ltd.) v. International Motor Traffic Synd. (Ltd.) and others upon a motion by defendants to vary the terms of an order of Feb. 13 last.

Mr. AUSTEN CARTMILL, in support of the motion, reminded his lordship that the action was brought against defendant syndicate and the Brighton, Hove & Preston Omnibus Co. in respect of an alleged wrongful sale of certain electric motor 'buses and spare parts, and £800 was paid to the International Synd. in respect of the purchase-money. The original judgment did not deal with the spare parts, because everybody at the time thought the spare parts delivered to the Brighton Co. were comprised in a list (now exhibited to the order). It turned out, however, that the list only included a portion of the accessories. There was also a technical objection to the minutes of the order.

His LORDSHIP said that the list of accessories was an agreed list, and the case proceeded on that basis. It was conclusive, and he thought he ought not to leave open the question of whether the sale of all the articles in the agreement was wrongful.

Mr. COLEBRIDGE pointed out that the enquiry would have to go as to what really were the things included in the list.

His LORDSHIP said that would be left open, but the enquiry was not to include any articles that were in the list. He thought also that it should be made clear that the order was made on both the claim and counterclaim.

The minutes of the order were directed to be varied accordingly.

Dead Tramway Points.

At the Westminster County Court on 4th inst. the F.I.A.T. Motor Cab Co. sued London County Council for £5. 18s. 6d. damages to a motor cab alleged to have been caused by its running into an electric tramcar. Plaintiffs' case was that the tramcar got on to a dead point at High-street, Camden Town, early on the morning of Nov. 23 last, where it would have to stop without lights until pushed forward sufficiently for the plough to pick up the current again. It was very foggy, and one of plaintiffs' cabs, containing two gentlemen, ran into the rear of the car, both passengers being injured and the cab damaged to the amount claimed. Defendants

Digitized by Google

were negligent in not providing a permanent tail light as required by the Board of Trade.

For the defence it was said that the car was moving and lighted, and complied with the police and Board of Trade requirements. Dead points were authorised, and it was inevitable that the lights would go out when dead points were crossed.

After hearing the evidence and legal arguments, his HONOUR held that the car was stationary and unlighted, and found for plaintiffs, with costs, on the ground that if the car had been an ordinary vehicle it must, when stopped, give some warning to the traffic following it.

Trade Union Funds.

In an action brought by Mr. John Wilson against the Amalgamated Society of Engineers and its trustees to restrain them from applying their funds for Parliamentary and other purposes, Mr. Justice Parker, in the High Court, recently delivered judgment in favour of the plaintiff. His Lordship said the judgment would go substantially in the form of the Osborne case in the Court of Appeal. In the present case the rules purported to give power to levy for the purposes of elections of municipal and other local bodies. Every argument in the Osborne case seemed to apply to such elections also, and the judgment must, therefore, be framed so as to extend to elections of municipal or other local government authorities, not including boards of guardians.

PARLIAMENTARY INTELLIGENCE.

L.C.C. TRAMWAYS AND IMPROVEMENTS BILL.

A Select Committee of the House of Commons, presided over by Sir Luke White, has been considering this bill during the past week.

After hearing the chief officer of the tramways (Mr. A. L. C. Fell) the committee agreed to a clause being inserted which will enable the Council to erect tramway shelters (with the consent of the local authority) at different points on the routes.

A clause authorising the Council to run reserved tramcars for women workers and Sunday school and other parties was also passed.

In regard to the proposal to construct a tramway along Edgware-road to the Marble Arch, Mr. POLLOCK, K.C., stated that the tramway would start at a junction with the Middlesex County Council tramways at Cricklewood, and terminate at the Marble Arch end of the Edgware-road. The total length would be nearly 2½ miles and the total cost £116,500. The cost of the proposed widenings (as settled between the different authorities) was £277,000, of which £246,000 was for land. At the Marble Arch terminus there would be a single line 25 yds. long, leaving a roadway on each side 20 ft. wide.

Mr. M. FITZMAURICE, C.M.G., chief engineer to London County Council, gave evidence in support of the bill. In cross-examination witness did not agree with the report of the Home Office, which was adverse to the construction of such a tramway owing to the difficulty of regulating the traffic. According to the report, a dead-end terminus at Marble Arch would be dangerous, particularly on the occasion of great meetings in Hyde Park.

In reply to Mr. Lankester, K.C., witness said there was no intention to put forward a proposal eventually for continuing the tramway through Park-lane. He had never recommended or thought of any such extension. He had thought of a scheme for carrying a tramway under Hyde Park.

On Wednesday Mr. EDWARD WHITE, Chairman of the County Council, said that this tramway was much wanted in the public interest. Apart from the tramway, the proposed widenings would be of immense advantage. They were in negotiation with the Middlesex County Council as to the amount they would contribute to the cost of widenings. He had every reason to suppose that the widenings would cost £300,000, and then there would be the cost of laying the lines. Asked whether he thought the intended dead-end at Marble Arch was a suitable place for a terminus, Mr. White replied that it was just about the best that could be picked in London, because the space that would be occupied by the single line was not wider than the refuge which was already there.

Mr. A. L. C. FELL stated that the journey between the Marble Arch and Cricklewood would occupy about 25 minutes, and the fare for the whole distance would be 2d., with ½d. and 1d. stages. He would advocate a tramway down the Strand.

Mr. MACASSEY said that, so far as the County Council were concerned, it must be the whole scheme or nothing.

The Committee adjourned.

In a report on the above bill, by the Commissioner of Police it is stated that in streets in which tramways are laid the general traffic invariably increases. This is especially apparent in the suburbs, in the main streets of which the general traffic appears to increase pari passu with the facilities offered for transit.

When tramways are laid streets tend to change their character from residential to mercantile. The fast-moving tramcars have the effect of diverting other vehicular traffic to the sides, so that any overflow from the pavement to the road becomes impossible or dangerous. Accordingly, when tramways are laid, pavements—instead of being reduced, require rather to be widened to provide greater accommodation. It appears, therefore, desirable that when a new tramway scheme is proposed the whole effect of the scheme should be considered beforehand, and the necessary provision made for the increased traffic by maintaining or providing sufficient width of footway, and, if necessary, by the widening of the street.

The Edgware-road and other portions of the Council's scheme of tramways extension are criticised, and suggestions as to street-widening, &c., are made.

GREATER LONDON RAILWAY BILL.

A Select Committee of the House of Commons (presided over by Sir J. Compton-Rickett) commenced the hearing of this Bill.

Mr. J. D. FITZGERALD, K.C. (for the promoters) said powers were sought to construct a railway 57 miles in length to pass in a semi-circle round London north of the Thames, connecting with all the existing railways and with the Victoria and Albert and Tilbury Docks. The proposed line would begin at Feltham with a junction with the London & South-Western line, and give a connection via Clapham Junction with the lines south of the river. Passing through Southall and Northolt, connection would be made with the Great Western Railway, and the route to Birmingham, at Sudbury with the Great Central, at Wembley with the London & North-Western line and with the Metropolitan & Great Central, at Hendon with the Midland, and at Finchley with the Great Northern. Getting on to the Great Eastern there would be junctions with the Cambridge and Colchester lines, and proceeding eastwards the line would end at Tilbury Docks. Connection from Barking, through East and West Ham, would be made with the Victoria Docks. By means of these connections (said counsel) the dock traffic to and from the Midlands and the North could be transitted without entering London. The proposed line would also form a desirable route for the interchange of North and South London traffic, and for the traffic arising from the establishment of the factories and works on the line of route. A representative of the War Office would tell the Committee how advantageous the line would be for the movement of troops. The promoters thought a share capital of £4,000,000, with the usual one-third borrowing powers would suffice. That was not a novel proposal, as on three occasions a similar scheme had been before Parliament, and on two occasions had been sanctioned. The opposition to the Bill came mainly from railway companies, and was not in the public interest. The promoters were Lord Weardale, Sir Douglas F. R. Dawson, Col. Ivor Phillips, the Hon Arthur Stanley and Mr. H. Mallaby-Deeley.

Mr. W. FOXLEE, C.E., consulting engineer for the scheme put the expenditure on works and contingencies at £2,252,366, and on land at £1,453,202. The average would be £64,116 per mile of double line, or for works £38,972 per mile.

In reply to the Chairman, Mr. WEDDERBURN, K.C., said the land proposed to be taken would allow stations to be within the limits of deviation and the positions would be arranged with local authorities. The promoters had arrived at an agreement with the Port of London Authority.

Mr. BALFOUR BROWNE, K.C., called attention to the Report of the Commissioner of Police to the Home Office in which the proposed bridges over main roads were represented as too narrow and the gradients as too steep.

Mr. FOXLEE said the requirements of the report could be complied with at an increased cost of £60,000 for the bridges. There would be little difficulty in altering the gradients to 1 in 30. Negotiations were proceeding with the L. & S.W. Co. in reference to a junction at Feltham. No arrangement had been made for junction with the Great Eastern line. The tramways on the route would not be competitors for traffic, but would act as feeders for the new line.

On Tuesday Lord Ritchie, Chairman of the Parliamentary Committee and Port of London Authority, said the Authority were spending considerable sums in deepening the river, and had under consideration large extensions of the Victoria and Albert Docks. He expressed no opinion on details of the present scheme, but as it afforded additional railway facilities the Authority were in favour of it.

General G. V. KEMBALL, President of the War Railway Council and Director of Movements and Quartering for the War Office, said from a general military point of view the line would be advantageous.

Sir T. COURTENAY WARNER, M.P., said the line would be an enormous advantage to Walthamstow and the working-class population.

Mr. S. FAY, general manager of the Great Central Railway Co., said he did not see that the proposed line would be of any particular advantage to the Great Central Co., and he was not prepared to support the scheme on that ground.

Mr. W. FOXLEE, C.E., consulting engineer for the scheme, gave further evidence.

The Committee adjourned.

MIDDLESBROUGH, STOCKTON AND THORNABY TRAMWAY BILL.

On Monday a Committee of the House of Lords, presided over by Lord Sanderson, commenced the hearing of this bill.

For the promoters, Mr. BALFOUR BROWNE, K.C., said the bill would extend the time for the construction of tramways authorised in 1904 and some powers which were extended in 1907. In consequence of a series of tolls demanded along the line of route of the proposed tramways the promoters had found it impossible to proceed with the tramways, and now asked for an extension of time, the renewal of certain powers in one case where they had lapsed, and power to acquire compulsorily and extinguish the tolls on the roads.

After the Committee had heard the arguments of counsel for Middlesbrough Corporation and other petitioners against the bill, they decid

Digitized by Google

to hear petitioners in regard to new facts which had occurred since 1907 to make revival and extension of the powers granted under the 1907 Act objectionable, and also as regards objections to new provisions contained in the bill.

Mr. SAMUEL WHITE, a director of the Imperial Tramway Co. (the promoters), gave evidence, and said they were asking that their powers might be kept alive in order that time might be given for coming to an arrangement with regard to the tolls.

In cross-examination, he said he did not think it was worth while going on with the bill if the municipal authorities declined to assist the company in extinguishing the tolls, and he declined to give any guarantee whatever that the scheme in the bill would be carried out within a certain time.

Mr. PAGE, K.C. (for Middlesbrough Corporation), said under no circumstances would Middlesbrough Corporation enter into an arrangement with the promoters for the purchase of the tolls, or contribute towards the expenses for which the company had made themselves liable under the Acts of 1904 and 1907.

The CHAIRMAN announced that the Committee had decided to allow the bill to proceed subject to certain clauses as to the completion of the works and the extinction of the tolls being adjusted.

MATLOCK DISTRICT RAIL-LESS TRACTION BILL.

A House of Lords Select Committee, presided over by the Duke of Bedford, commenced the consideration of this bill on Wednesday.

The bill proposes the incorporation of the Matlock District Rail-less Traction Co. (to which Messrs. W. H. Collier, F. Douglas Fox and Thos. Bell and others have agreed to subscribe capital) with a capital of £5,000 and £5,000 borrowing powers to equip and run electric rail-less trolley cars between Matlock and Matlock Bath and the Market Place, Cromford, about 2¼ miles.

Mr. WEDDERBURN, K.C. (who with Mr. Hutchinson, K.C., and Mr. Crundall appeared for promoters), said the cars would weigh 3¼ tons empty and 5 tons full. The promoters offered to pay Derbyshire County Council £50 per mile per annum for additional upkeep of roads which the County Council said would be necessitated by the use of the rail-less trolley cars. The County Council opposed the Bill on the ground that the roads were steep and narrow, that the promoters were strangers in the district, and that no time was proposed to be fixed by the bill for the completion of the works.

Mr. J. B. HAMILTON, general manager of Leeds Corporation tramways, gave particulars of the Leeds experimental rail-less system. He said a return overhead wire was used. This was a requirement in all cases where no rails were used. He also described the systems in use in Austria and Italy. In Vienna the operation of the cars was simplicity itself, and the public were very pleased with the system. There was a range of deviation of about 15 ft. The overhead construction cost from £1,200 to £1,500 per mile, and the vehicles from £700 to £800 each. The cost of operation at Vienna was about on a par with ordinary tramways of the same carrying capacity. He thought they had reached the same point of reliability in trackless trolley traction. It was particularly suitable for thinly populated districts. A minimum of road-wear was caused by such a system. In the case of the Leeds rail-less cars he reckoned the margin of profit at ¾d. per car-mile, and the cost of working at 12d. per car-mile, without a conductor. If a conductor were necessary that would add about 1d. per mile. He did not know that if a generating station were put up at Matlock the cost of current would be higher than at Leeds (about ¾d. per unit). There had been no accidents at Vienna where part of the system had been working about six years. There was no more risk in insulating rail-less cars than ordinary tramcars. He agreed with Mr. Hutchinson that electricity could be generated by means of a water-power engine (which it was stated the company proposed to use) at ¾d. per unit.

Mr. I. E. WINSLOW (consulting engineer for the scheme) thought the proposed system would be of benefit to the neighbourhood. He agreed with Mr. Hamilton's evidence. There was a large traffic on the road over which it was proposed to run. Two cars would give about 20-minutes service, and he estimated the receipts at about £2,500 per annum. Profit would be about 2d. per mile. Four or five extra cars should be put on at holiday time, and this would increase the revenue by £1,500 per annum. The total expenditure, including the cost of the Act, was put at £16,450. The annual profit was estimated at about £1,200 (7 per cent. on the capital). Cost of working would be 6d. per car-mile. On the narrowest roadway on the proposed route was between 12 ft. and 15 ft. wide.

Evidence in opposition to the bill was given yesterday (Thursday) by witnesses called on behalf of the Derbyshire County Council and the Matlock Bath and Scarthin Wick District Council.

Automatic Printing Telegraph Instruments.—In the House of Commons, on Tuesday, Captain NORTON, Assistant Postmaster-General, stated, in answer to a question, that the high first cost and maintenance charges of automatic printing telegraph instruments were always be a bar to their employment where the traffic was not large, but he hoped to extend their use at the more important offices. Ordinary typewriters to be worked by the receiving telegraphists were being tried at some other places, but there were difficulties in the way of their general introduction.

Telephone Employes.—In the House of Commons on Thursday last week, the Postmaster-General stated, in reply to a question, that the general conditions under which employes of the National Telephone Co. were to be transferred to the Post Office were stated in the Memorandum read in the House on Aug. 9, 1905, by the then Postmaster-General. The bill, which he hoped shortly to introduce, would contain provisions respecting pensions. The question of the value to be attached to service under the company for purposes of seniority and for other purposes was still under consideration, and he was not yet able to make any further statement.

Coal Mines Bill.—The Grand Committee of the House of Commons, presided over by Mr. Eugene Wason, has been considering this bill, but up to the present only 13 clauses have been dealt with. These clauses relate to the appointment and qualifications of managers.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

March 6, 1911.

5,521 SUMNER. Current graduating devices or resistances.
5,530 MICKLEWOOD. Actuating gear for magnetos and dynamos.
5,563 MURRAY. Supplying electricity to consumers on the maximum demand system.
5,564 CROWE & BRITISH L.M. ERICSSON MFG. CO. Electric conctact keys or the like.*

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aston.—The accounts of the electricity department for the year ended March 31 were approved by the Corporation last week.

The total income was £32,880, against £30,065 in the previous year. After deduction of working expenses, interest, loan payments, &c., the net balance was £3,742. Altogether £4,068 is available, of which £3,600 is to be devoted to relief of rates.

Bampton.—The Urban Council have resolved to substitute electric lighting for the oil lamps at present used for public lighting.

Blackburn.—Last week the Council resolved to invite tenders for extensions of the electricity works to meet next winter's probable demand. Estimates amounting to £45,170 were approved and sanction to borrow this sum has been applied for.

Bognor.—The Board of Trade have notified the Council that the district has been excluded from the area scheduled in the provisional order granted to the Chichester Electric Light & Power Co.

Burnley.—The Tramways Committee recommend the expenditure of £14,650 on the construction of an additional length of tramway.

Burton-upon-Trent.—The L.G. Board have sanctioned a loan of £1,750 for house services and transformers.

Colne.—The Council have applied for sanction to a loan of £2,000 for extensions of mains.

Coronation Illuminations.—A meeting of permanent residents decided last week to illuminate the front of *Douglas Bay* (Isle of Man) by means of electric lamps during the Coronation season, at an estimated cost of £680. *Kingston-on-Thames* Corporation will supply current at 1½d. per unit for illuminations during Coronation week, with a small additional charge for a special meter, &c. Canbury Gardens, Kingston Bridge and the Queen's Promenade, Kingston, are to be illuminated by 17,000 electric lamps, at a cost of £100.

Country House Lighting.—The Marquis of Northampton is having electric lighting plant installed for the lighting of Castle Ashby.

It is stated that most of the fine old colza lamps at Castle Ashby which have been so much admired in the past are being converted to electric lamps connected to wall plugs. His Lordship has further decided to instal the electric light in the church, utilising the beautiful old Viennese bracket lamps. The work will be begun immediately.

Donaghadee (Ireland).—A Board of Trade enquiry was held last week by Mr. G. B. Deane, J.P., into the application of the Council for an electric lighting provisional order.

The town clerk (Mr. D. WALKER) gave evidence as to the financial position of the town, &c.

Dr. GEORGE GIBSON, J.P., chairman of the Council, gave evidence as to the present lighting of the district and the necessity for lighting portions of the district to which the gas mains did not extend and where the gas company would not put down mains. He thought an electricity scheme would prove a success in view of the fact that it could be used for pumping the water for the town supply

Mr. ARTHUR WILKINS (Messrs. Wilkins & Bowden) said his firm drew up a scheme for the electric lighting of the entire district, and estimated that, from results shown by other towns of a similar size, a profit of £290. 10s. could be made with their scheme after paying expenses, including interest and sinking fund.

Other evidence having been given in favour of the scheme,

Messrs. J. C. MacGowan (secretary) and R. M'Conkey and J. H. Barrett (directors of the gas company) gave evidence in opposition.

Dover.—The Council have received sanction to a loan of £2,300 for extensions of mains, services, &c.

Dublin.—The L.G. Board inquiry into the application of the Corporation for sanction to borrow £128,129 for extensions of the electricity undertaking was concluded on Saturday.

The evidence in favour of the application was given in THE ELECTRICIAN on April 29 and May 5. The Rathmines and Pembroke Drainage Board opposed the application.

Mr. W. W. Murphy gave evidence in opposition, and more particularly as to the unsuitability of the Pigeon House site, the cost of working, &c.

At this stage it was announced that the Electric Light Committee and the Drainage Board had come to terms.

Mr. MARK RUDDLE, city electrical engineer, was recalled by the inspector (Mr. Cowan) in reference to the plans for extension at the Pigeon House. He said he did not see any reason to change the plans at all, except in points of detail. An intermediate station between the Pigeon House and Fleet-street would increase the chance of a breakdown, and add to the expense, and the Corporation desired to work the station as economically as possible. He said, having made his protest against the site, he had done his best to make the scheme a success.

Dundee.—The Council have adopted a scheme of universal 1d. fares on the tramway system and the ½d. stages have been reduced to 880 yds.

Electricity in Gold Mining.—The chairman of the Balaghat Gold Mining Co. (Mr. John Taylor) stated at the meeting last week that from the beginning of last November, under the terms of their agreement with the Mysore Government, the contract rate for 181 H.P. supplied electrically under the Cauvery scheme was reduced from £24 to £10 per horse-power per annum.

Electricity in Pottery Works.—Messrs. T. G. Green & Co., Church Gresley, have recently installed electric power and lighting plant.

Previously the four factories of the firm were worked separately, a number of boilers and engines being utilised. All these have been discarded, and a central power house erected. The boiler house contains Lancashire boilers (by Ruston, Proctor & Co.) which work at a pressure of 150 lb. They are fed by forced draught, automatic-feed stokers by Belliss & Morcom, who have also supplied a 375 H.P. high-speed engine. The electrical work has been carried out by Messrs. Crompton & Co., and consists of a 250 kw. three-phase alternator, and 14 motors, from 50 H.P. to 5 H.P., are installed for various work. Difficulties were at first experienced with the milling portion, owing to the starting load being so extraordinarily heavy, but the few difficulties were successfully overcome, and at the present time all the four works are being driven electrically, and entirely to the proprietors' satisfaction. The works are electrically lighted throughout, the contract for this work having been sub-let to Mr. Richards, of Burton.

Hammersmith (London).—Tenders are to be invited for a feed-water-heater at a cost of £250. 68 further gas lamps in side streets are to be converted to electric lighting at a cost (including cost of posts) of £392. 14s.

Hastings.—An inquiry was held on Friday into the application of the Council for sanction to borrow £1,789 for extending the electric supply mains to the workhouse and to the sanatorium.

The Acting Town Clerk said the Guardians had agreed to take current for five years, and it was estimated to supply 10,000 units per annum. Deducting expenses there would be a net income of £181.

The local gas company opposed, and the assistant engineer to the company gave evidence in opposition. The witness admitted, in cross-examination, that he used electric lighting for part of his offices.

Hornsey Electrical Exhibition.—On Monday the Mayor of Hornsey (Coun. A. A. Yeatman, J.P.) and the Mayoress opened an exhibition of electrical and domestic apparatus at the Athenæum, Muswell Hill.

The exhibition is organised by the Electricity Supply Committee, and a number of local and other exhibitors displayed electric motors, cooking and heating apparatus, lamps, fittings, &c.

After declaring the exhibition open the Mayor gave a sketch of the progress of the electricity department. They started, he said, to supply current in 1903. They had in the first year 445 consumers and 26,000 8 c.p. lamps connected; in 1910 they had 1,750 consumers and 92,000 lamps; while now they had over 2,000 consumers and over 100,000 8 c.p. lamps. The number of units supplied increased every year in spite of metal filament lamps. They had £2,000 profit last year.

Light Railways.—The Board of Trade have confirmed the Doncaster Corporation Light Railways (Extension) Order, 1911.

A scheme is being prepared for the construction of a light railway from Ashton-under-Lyne to Bury.

It is intended to run the light railway across part of Ashton Moss, past Daisy Nook and over Buckley Hill to Failsworth. From Failsworth the line will go near Middleton and on to Bury.

London County Council.—On Tuesday an estimate on capital account of £1,675 was approved of for sand crushing machinery for the tramways.

Renewal of Special Trackwork.—It was reported that Hadfield's Steel Foundry Co. had agreed to supply the special trackwork required for renewals during the present financial year for £13,245. 15s.

Marble Arch Tramways.—Mr. Stuart Sankey brought up a report of the Parliamentary Committee which stated that negotiations were proceeding with Hampstead Borough and Middlesex County Councils with regard to street widening in Kilburn and Brondesbury and other matters, and these involved such large and additional obligations on the part of the Council that the scheme would be of a much more costly nature than was anticipated. If the negotiations were unsuccessful the Council would be under the necessity of withdrawing the scheme from the bill. The

Digitized by Google

original estimate for street widenings in Hampstead was £95,000; it had now been raised to £277,000, and Hampstead Council were putting forward further requirements which would increase it to £310,000. Paddington would probably ask for widenings which would cost £150,000, and the cost of constructing the line was estimated at £120,000.—Report adopted.

Luton.—The Council have received sanction to a loan of £13,510 for additional generating plant, mains, &c.

Metropolitan Water Board.—At the meeting on Friday the Works and Stores Committee reported that proposals had been placed before them for an extension of the electric lighting at the Hampton and Surbiton stations.

The total cost of the work at Hampton Station, including plant, wiring, lamps, &c., will be £1,400, and the upkeep of the new plant, with interest upon the capital, will be £260 per annum. The cost of lighting this portion of the station by gas is over £400 per annum, so there will be a considerable saving. Surbiton Station is lighted by gas, and it is proposed to instal electric lighting plant and apparatus at a cost of about £1,675. The average annual cost of the existing gas lighting is £680, and the cost of maintenance of the proposed electric plant (with interest) will be £320. All the work is to be carried out by the Board's workmen.

Oulton Broad.—The Council have referred back to the Electric Lighting Committee a public lighting scheme prepared by Mr. J. Forrest Hare. The estimated cost is £2,868. Overhead cables are proposed for a portion of the district.

Penmaenmawr.—The Council have decided to complete the scheme for the lighting of the promenade by flame arc lamps.

Portrush (Ireland).—As the Council cannot come to terms with the local gas company re purchase of the gas works, it has been decided to take steps to erect electricity works. Messrs. Millar, Wilson & Pegg are consulting electrical engineers to the Council.

Portsmouth.—The L.G. Board have been asked to sanction the borrowing of £700 towards the purchase of superheaters for the generating stations.

Presentations.—On his marriage Mr. T. Hall, borough electrical engineer, Burton-on-Trent, has been presented by the staff with a clock and silver butter dish.

The staff of Middlesbrough electricity works have presented a travelling trunk to Mr. H. E. Pawson, senior charge engineer, who is leaving to take up a position abroad.

St. Annes-on-the-Sea.—The Council have referred back a proposal to give the electrical engineer (Mr. T. D. Clothier) a bonus of 5 per cent. on profits over those of last year.

South Shields.—An inquiry was held on Wednesday into the application of the Corporation for sanction to borrow £10,080 for extensions of the electricity undertaking.

Of that amount it was proposed to borrow £7,580, the balance of £2,500 to be taken out of the reserve fund. The North-Eastern Railway Co. and Smith's Dock Co. opposed on the ground that they want three-phase alternating current for power at their docks, and that the only way in which they could obtain such a supply was to induce the Corporation—whose under their own scheme could not provide such current—to take it from the County of Durham Electric Power Supply Co. The County of Durham Co. had offered to instal plant in the Corporation's station to provide twice the power the Corporation's new scheme provided at a cost of £15,500, the Corporation paying £10,080, which they had proposed to expend on their own scheme, the whole of the plant to become immediate property of the Corporation.

Swansea.—There are now over 2,000 consumers, representing the connection of 154,225 8-c.p. lamps, connected to the electricity mains.

Swindon.—The Council have applied for a loan of £3,510 for extensions to the electricity works.

Telegraph Communication with the Continent.—A deputation from the Liverpool Chamber of Commerce and other commercial interests waited on Tuesday upon the Postmaster-General to urge an improvement in the telegraphic communication between this country and the Continent.

In reply to the suggestions of the deputation, Mr. HERBERT SAMUEL said attention had been drawn to the delay in the telegraphic communication between London and Liverpool, and considerable improvement had since been effected by the installation of new apparatus. The average delay now was 3½ minutes, which, he thought, could not be regarded as unsatisfactory. With regard to inland telegrams, he thought that telegrams should be all urgent. With respect to foreign telegrams, he was by no means satisfied with the service that existed between the commercial centres of England and the chief cities on the Continent. The delays that took place between Liverpool and the Continent, were owing to divert a large part of that additional business to the Post Office through the Central Telegraph Office, and thereby to relieve congestion on the direct wires. After many experiments they had made they thought was a really effective apparatus—the multiplex—which would enable a much greater use to be made of the wires than at present.

West Ham.—The Electric Lighting Committee reported on Tuesday that they had approved proposals of the borough electrical engineer (Mr. H. H. Couzens) for extensions of the generating plant, &c., at a cost of £59,000. The report is to be referred to the Finance Committee to report as to the provision of the necessary funds.

Mr. Couzens' proposals include river service pipework (£8,500), buildings (£9,500), 5,000 kw. turbo-alternator set, with condensers, &c. (£14,000), boiler plant and auxiliaries (£12,400), pumps, tanks, pipework, &c. (£3,100), coaling plant (£3,000), contingencies (£2,500) and general mains for two mains (£6,000). The coaling plant is inadequate, and it is proposed to instal a telpher scheme beside the existing runway of the Temperley transporter, such telpher to deal with 60 tons of coal per hour. Several of the items in the list of plant are most urgently needed, and the additional boiler plant should be in operation for next winter's load.

Woodbridge (Suffolk).—At the Council meeting last week Mr. Edmund Charrington's proposals for the supply of electricity for light and power in this district were referred to the Electric Committee for report.

Dinners.—On Saturday last a farewell dinner was given in London to Mr. Evan Parry, B.Sc., who is leaving England to take up an appointment as electrical adviser to the New Zealand Government, in connection with the hydro-electric developments which that Government propose to carry out.

Between 70 and 80 friends and well-wishers were present, amongst whom were Dr. H. F. Parshall (in the chair), Mr. Robert Hammond, Mr. W. M. Mordey, Mr. A. P. Trotter, Mr. Palliser, Mr. Tegetmeier, Mr. James Devonshire, and other gentlemen representing every branch of the engineering profession. Letters were received from Sir Joseph Ward, Prime Minister of New Zealand, and Sir William Hall-Jones, High Commissioner for the New Zealand Government, expressing regret at being unable to be present, and telegrams were received from Mr. S. Z. de Ferranti, Mr. C. H. Merz, Mr. T. O. Callender and others regretting unavoidable absence.

The toast of "The Guest of the Evening" was proposed by Dr. PARSHALL, who pointed out that Mr. Parry had been closely associated with him for the last 18 years, during which time schemes involving the expenditure of many millions of money had been carried out by them, extending as far as California, Mexico and Canada. He felt deeply the severance of a connection which had always been extremely cordial and friendly, and congratulated the New Zealand Government on having secured the services of a man so eminently qualified to carry through the schemes contemplated by them.

Mr. MORDEY, Mr. TROTTER, Mr. HAMMOND and Mr. DEVONSHIRE also spoke in eulogistic terms of Mr. Parry, after which a presentation was made to him of a handsome silver cup, on which was inscribed the names of the hosts.

Mr. TEGETMEIER, chairman of the Auckland Tramways, gave Mr. Parry a hearty welcome to New Zealand, and an enjoyable evening terminated with a vote of thanks to the chairman and to Mr. Edward Moss, the organiser of the dinner.

Mr. F. W. Roberts, late district manager of the National Telephone Co. at Brighton, has been entertained to a farewell dinner by the local staff of the company, on his leaving to take up the appointment of engineer-in-chief to the United River Plate Telephone Co. at Buenos Ayres.

Mr. C. F. Moorhouse, district manager of the National Co., presided, and was supported by the principal members of the staff. In proposing Mr. Roberts' health, Mr. Moorhouse referred in eulogistic terms to Mr. Roberts' work in the district.

Mr. Roberts was also presented with a gold watch and a silver tea service.

Sports.—The first annual sports of the Silvertown Rubber Works Athletic Club were held last Saturday at Canning Town in splendid weather. There was a large attendance, and the events on the programme kept spectators interested from start to finish.

The chief event was the Marathon race of 10½ miles for the Gray challenge cup and gold medal. This was the third year of this race. The result of Saturday's race was that the cup remains in the possession of G. Peters, who has been the winner on each of the three occasions of the race. There were 11 starters, six finishing, and the race proved an easy thing for Peters, who won in 64 min. 59 sec. The 100 yards sprint was won by A. Baker in 11 sec., and the 440 yards race by the same runner in 58⅖ sec. E. Cole won the three miles in 17 min. 50⅕ sec.; T. Tyrie was successful in the one mile in 5 min. 22⅘ sec; T. Willis won the one mile cycle race in splendid style by half a wheel, in 2 min. 45⅗ sec.; the tug-of-war, which produced the greatest rivalry between the various shops competing, was won by N department; FN team won the one mile relay; B. Knight the 100 yards race (under 18); D. Young the 300 yards handicap race for boys under 14, sons of employés; Miss N. McAlenon the 50 yards skipping race; and Miss L. Kerry the 50 yards thread-the-needle race.

At the close Mrs. P. M. S. Brodie, wife of the president, presented the prizes to the successful competitors. During the afternoon a capital programme of music was rendered by the Graysilver Military Band, under the conductorship of Mr. J. H. Parnum. This band, which has only been formed about a year, is coming along well.

COLONIAL AND FOREIGN NOTES.

Brazil.—The Minister of Public Works has given orders for fresh tenders to be invited for the equipment of a telephone system between Rio de Janeiro and Sao Paulo.

The Cia Braziliera de Energia Electrica have been granted a concession for laying a double line of submarine electric power cables from Nectheray to Rio de Janeiro.

Budapest.—The Traffic and Finance Commission of the Municipal Council have agreed to acquire the bulk of the Budapest Electric City Railway shares.

French Telegraph Service.—The London "Daily Telegraph" of 6th inst. has the following interesting note on the work of M. Queinnec, a member of the telegraph staff of the French Imperial Service :—

Fifty million francs, or £2,000,000, has been saved to the French telegraph administration by a zealous subordinate, M. Queinnec. Incidentally, it also reveals the fact that subterranean telegraph lines have gone completely out of vogue with the engineers of the public telegraph lines. More than 30 years ago France had an elaborate system of subterranean lines. In 1879 Paris was connected with all the large towns by underground wires, which were *proof against* the ordinary disturbances of the elements. But other difficulties arose, and in 1880 none of the lines were working. They had been rapidly worn out, and the repairs would have entailed extraordinary expense. For 10 years the underground wires were *not used*, and in 1890 a report to the Budget Committee advised their total abandonment. It was then that M. Queinnec, a postal employee, came forward to save the lines, which had cost £1,600,000. He had read the report, and he called on the Under-Secretary for Posts and Telegraphs with a scheme for utilising the lines. He was received, listened to, and given a commission to execute some of the repairs at a small cost for the sake of a trial. He set to work, in spite of the scepticism of the engineers, and succeeding in thoroughly repairing one line after another. Better still, he discovered a way by which their working was improved, and the material saved from wearing out. As a result, Paris was again in underground telegraphic connection with all the great towns and military centres, except those of the eastern frontier, on which M. Queinnec had not yet received permission to work. He had saved £1,600,000 to the Treasury, and well deserved the rise in his salary which he received in consequence.

Last year the utility of his plan was still more clearly demonstrated. Many of the suburbs were cut off from Paris during the inundations. Paris had been endowed years ago with a system of subterranean wires, which completely encircled it. M. Queinnec had not yet touched these lines, which had cost some £400,000. He proposed to make them serviceable again without delay. They had been so long abandoned that the plans of some of them had actually been lost. He set to work, and in a short time all the lines were again fit for service. M. Queinnec had saved the Administration another £400,000 worth of wires. He suggested a very simple method for preventing deterioration. When in operation the wires were to carry the negative current, and the positive current when at rest. The opposite had been done before, and this was, it seems, bad for the wires. The model employee who had thus saved some £2,000,000 to the State received another rise in his salary and was decorated last July, and now the Budget Commission has proposed that he should be made inspector-in-chief of all the subterranean telegraph lines.

Holland.—It is stated that a proposal is on foot for the construction of an electric tramway 11 miles in length, from The Hague to Leyden via Wassenaar, power being taken from The Hague central station.

Italy.—The Societa-Anon. della Tramvie Elettriche della Provincia di Salerno have obtained a concession for an electric tramway in the Valle di Pompei.

Montenegro.—The Montenegrin Parliament has approved the concession for the erection of hydro-electric works of 12,000 H.P. capacity which are to be equipped with the aid of British, Belgian and Swiss capital.

South Africa.—"South Africa" states that there are indications that the electric tramway scheme for linking up Boksburg and Germiston will soon be proceeded with. Boksburg Council have framed a schedule of the route in their own area and the negotiations with Germiston for a joint scheme appear to be favourably received. The estimated expenditure by Boksburg Council is £110,000 for about 7½ miles of tramways, the construction of a subway between East Rand station and Vogelfontein crossing, and the widening of the subway at Boksburg North-road.

Wireless Telegraph Notes.—The Russian Ministries of Ways of Communication, Interior and Mines, have collectively submitted to the Duma a bill providing for measures to be taken for facilitating commercial communication between Western Siberia and Western Europe, via the Arctic Ocean. The scheme involves the construction of four radio-telegraphic stations on the coasts of the Kara and White Seas, the exploration of the Kara Sea coasts, and the exploration of the country from the lower course of the river Ob to the coast of the Arctic Ocean with a view to the construction of a railway line. Credits to the amount of 160,000 roubles (about £16,900) are asked for the current year, and to the amount of 180,000 roubles (about £19,000) for 1912 for the purpose of completing the radio-telegraphic stations.

What is described as the first communication between France and Switzerland by wireless telegraphy took place last week, when the station on the Eifel Tower at Paris held converse with the Chaux de Fonds on the other side of the Jura Alps, a distance of about 200 miles.

The great Durbar, which is to be held by King George at Delhi in the autumn of 1911, is to be on a grand scale, and we learn that amongst the features of the Durbar will be the erection of wireless telegraph stations at Delhi, Calcutta, Allahabad and Simla. It is announced that the Marconi Wireless Telegraph Co. have received orders for the erection and equipment of these stations at an estimated cost of £50,000.

It is announced that the Marconi wireless telegraph station at Slangkop, south of Cape Town, erected for the Government of the Union of South Africa, has been opened and that communication has been established with several of the Union Castle line steamers, the distance in one case being 1,500 miles.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited (up to June 14) for supply of cable, ironwork, c.i. pipes, iron or steel poles, phosphor bronze wire, &c., to the Postmaster-General's Department. QUEENSLAND; and (up to June 27) for supply of 1,400 protectors for use on main distributing frame at magneto exchanges to the Postmaster-General's Department, VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W. See also advertisements.

SOUTH SHIELDS Corporation want tenders by May 24 for supply and erection of 1,500 kw. high-pressure steam turbine (with surface condenser and pumps) coupled to 1,000 kw. d.c. generator (with switch panel, &c.) and 1,100 kw. a.c. generator (with switch panel, &c.). Specification, &c., from the Borough Electrical Engineer.

HULL Corporation require tenders by noon May 24 for extension of Sculcoates-lane generating station and New George-street substation.

HACKNEY (London) Council require tenders by 7 p.m. May 25 for supply of 100,000 pairs of yellow flame carbons during the year to March 31, 1912. Specification, &c., from Town Clerk.

LEYTON Council want tenders by May 17 for Coronation illuminations at the Town Hall and two branch libraries. Particulars from the Engineer.

HORNSEY Corporation want tenders by 4 p.m. May 19 for water tube boiler, automatic stoker, &c. Forms, &c., from Borough Electrical Engineer.

PORTSMOUTH Corporation want tenders by 10 a.m. May 22 for supplying and fitting 186 Mazda lamps in the Town Hall. Forms of tender from the Borough Engineer.

Tenders are invited up to July 25 for the supply of 12 section of a branching multiple magneto lamp signalling switchboard, &c. or one automatic or semi-automatic switchboard, &c.; and up to June 14 for supply of a branching multiple magneto lamp signaling switchboard at Ballarat, up to May 30 for the supply of one portable petrol-driven desiccating plant to the Postmaster-General

Digitized by Google

department in Victoria, and up to May 31 for the supply of 7,000 insulators and wire and line material to the Postmaster-General's department in SOUTH AUSTRALIA.; and up to June 14 for supply of a c.h. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA; and up to June 7 for the supply of 2 nauts single-core submarine cable to the Postmaster-General's Department, NEW SOUTH WALES. Tender forms, &c., from 72, Victoria-street, London, S.W.

Tenders are wanted by May 19 for supply of six 60 kw. single-phase transformers, and by May 26 for 1,024,000 arc lamp carbons and for 6,000 metal filament incandescent lamps for the City of MELBOURNE electricity department. Tender forms, specification, conditions of tender, &c., from the Agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter-square Buildings, London, E.C.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z. until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, &c. Specifications, &c., at the offices of the High Commissioner, 13, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. June 13, for the supply of electric lighting material, 12 accumulators and 400 cable distributing boxes and chemicals and glassware for batteries.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

The Controller of Stores, Post and Telegraph Department, WELLINGTON, N.Z., will receive tenders until 5 p.m. June 6 for supply of 70 tons g.i. telephone wire. Specification, &c., at 73, Basinghall-street, London, E.C.

Tenders will be received by the chairman of the Board of Control, City Hall, TORONTO (up to noon, June 6), for pumps and electrical equipment, screening, elevating and conveying apparatus, and cast-iron and indicating and recording apparatus for Venturi meters. Specifications, &c., from the City Engineer, Toronto, and can be seen by British manufacturers at 73, Basinghall-street, London, E.C.

FRANKFORT-ON-MAIN Corporation require tenders by May 20 for two 7,500 kw. steam generators with condensers.

BRUSSELS Municipality want tenders by May 19 for c.i. pipes for the electricity department.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Fabric and accessories for harnessing the water at rate of 7,000 litres per second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price (converted) £40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 4 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (in Italian) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

The following tenders have been accepted for 12 months' supply of stores and materials to Pontypridd District Council:—

Tramway Equipment.—British Thomson-Houston Co., armature coils, mica and copper segments, field coils, pinion washers, pinions and commutator nuts, grease box covers, gear case covers, axle caps, traction motor brushes, gear and pinion wheels, gear cases, trolley poles, trolley contacts, controller fingers and finger guards, trolley wheels and insulating sleeves; Malleable Steel Castings (Ltd.), armature bearing caps; Anti-Attrition Co., journal axle box and motor suspension bearings, trolley wheels and wheel bushes; Armstrong Oiler Co., oilers; Brecknell, Munro & Rogers, trolley heads, trailing and mechanical frogs and trolley collectors; Brecknell, Munro & Rogers, trolley head connectors and fuse boxes, &c.; Sykes & Sugden, connectors; Haslam & Schontheil, fuses and fuse bases, Obach cells, insulator bolts, &c.; British Insulated & Helsby Cables, service boxes and Reason cut-outs; R. W. Blackwell & Co., bracket hooks and brackets and galvanised steel span wire; Hay-Shaw Co., J. & P. arc lamp cut-out coils.

Lighting & Tramways Department.—Donovan & Co., bayonet holders and glass shades; E. Dewhurst & Co., beech, teak and walnut blocks; Haslam & Schontheil, cut-outs, Osram lamps, pear switches, rosettes, elbows, bends, tees, sockets, bushes and pipe clips, tapes, varnish paints &c.; S. M. Jones, casing and capping; Cryselco (Ltd.), metal filament lamps, tumbler switches; Siemens Bros. Dynamo Works, water tight fittings, Tantalum lamps and Langham shades; General Electric Co., swan-neck brackets; Ward & Goldstone, window brackets, plugs and cut-outs; Paxton & Co., C. G. and batten holders; Economic Electric Co., insulated hooks, conduit bends, bushes, sockets and pipe-clips; British Thomson-Houston Co., carbon and Mazda metal filament lamps and tumbler switches; Electrical Co., Luna burners; Imperial lamp Works, Brimsdown, metal filament lamps; India Rubber Co., plugs; British Westinghouse Co., tumbler switches, opal and green and opal shades, enamelled iron shades and counter weights; Johnson & Phillips, shell reflectors; J. H. Tucker & Co., d.-p. switches; S. D. Roberts, plate glass and destination and ventilator glasses; D. A. Webb, dash light glasses and red and green signal glasses; City Glass Co., J. & P. arc outer and inner globes and Reason globes; W. T. Henley's Telegraph Works Co., three-core and twin paper cables (in plain lead, armoured and bitumen); R. R. Todd, v.r. insulated 600 to 2,500 megohm Association cables and v.i.r. 600 to 2,000 megohm flexibles and v.r. insulated 600 megohm non-Association installation wires; British Insulated & Helsby Cables, v.r. insulated 600 megohm non-Association installation wires; Micanite & Insulators Co., press-spahn paper, Empire cloth, thin fibre paper and fibre washers; Siemens Bros. & Co., Mansville tape; British Westinghouse Co., or F. J. Down, Okonite and Blackley tape; British Electrical & Mfg. Co., Para strip.

St. Pancras (London) Council have accepted the following tenders:—Sloan Electrical Co., 112,500 12 in. and 37,500 pairs 10 in. arc lamp carbons, £470. 15s. 7d.; Siemens Bros. Dynamo Works, 37,500 pairs 12 in. and 12,500 pairs 10 in. carbons, £265. 18s. 9d.; Wm. Giepel & Co., "Oriflamme" carbons, £34. 4s.; "Luna" carbons, £13. 6s. 3d.; Union Electric Co., "Gilbert" carbons, £55; "Excello" duplex carbons, £37. 7d.; "Excello" cored carbons, £20. 6s.

Sheffield Council have accepted the following tenders:—

Ferranti Limited, supply and erection of switchboards for Chapel-lane and Princess-street sub-stations, £1,332. 11s.; W. T. Glover & Co., 100 tons of electrolytic copper wire bars and 200 tons lead (to be made up into cables as and when required within two years from placing the order) at current prices.

Luton Council have accepted the following tenders:—

Brush Co., 650 kw. exhaust steam turbo-generator, £2,495.10s., and 400 kw. ditto, £1,913. 5s.; Rees Roturbo Co., pump, £363; Babcock & Wilcox, tube clearner, £11.

Tonbridge Council have accepted the following tenders:—

Gwynnes Ltd., electric pumping plant for sewage works, £1,045; Western Electric Co., cables, &c., £1,032. 9s. 6d.; Seale, Austin & Barnes, wiring castle grounds for illuminations.

Deptford (London) Council have accepted the quotation of Wilkins & Son to fix electric light fittings at the New Cross branch library and provide lamps and shades at £32. 8s. 6d.

Wadebridge Council have accepted the tender of the local electric lighting company for public lighting on the Egloshayle side of the town.

Wolverhampton Council have accepted the tenders of Hadfield's Steel Foundry Co. for special tramway point and crossings, at £411, and that of W. Lucy & Co. for 300 street lamps and brackets.

Cheltenham Council have accepted the tender of Aiton & Co. for steam piping at £200, and that of Beattie & Co. for a Taylor-Scotson regulator at £95.

Tonbridge Council have accepted the tender of Gwynnes Ltd., for the supply of electric pumping plant at £1,045, and that of the Western Electric Co. for the supply of about 1,600 yd. electric cables at £1,032. 9s. 6d.

The Bastian Meter Co. have secured the contract for supplying Govan Corporation with 1½ and 3-ampere meters for the ensuing year.

St. Helens Council have accepted the tender of the Worthington Pump Co. for a centrifugal pump.

Gillingham Council have let the contract for wiring the fire station to A. Chapman.

The tender of H. S. Tett & Co. has been accepted by Faversham Council for wiring work at the sewage works.

Kingston-on-Thames Council have accepted the tender of Offer & Sons for Coronation illuminations, comprising 17,000 lamps, at £100.

BUSINESS NOTICES.

The new factory of the Electrical Apparatus Co. (Ltd.) at Vauxhall, London, is now completed. The new works have much greater accommodation and the new address of the company will be Vauxhall Works, South Lambeth-road, London, S.W. Telephone No. Brixton 1,975. The company state that the change has been necessitated by a large increase in their output of E.A.C. meters and motor-control gear.

Messrs. Carney & Pearn (Ltd.) announce that their Manchester telephone number has been changed from 4197 Central to 1279 Rusholme, and in order to deal with increased business they have a private branch exchange.

Digitized by Google

Messrs. Marryat & Place have appointed Messrs. Leslie & Co., 888, Hay-street, Perth, as sole agents for their lifts in Western Australia, and Mervyn W. Stevenson & Co., 188, Hereford-street, Christchurch, (N. Z.), as sole agents in New Zealand.

The agency of the Allgemeine Electricitats Gesellschaft, formerly held by Staerker & Fischer, has been transferred to the Australian Metal Co. (Ltd.), which company will represent the A.E.G. in the whole of Australia (except Western Australia) and New Zealand, the Western Australian agents being Couche, Calder & Co.

The Australian Metal Co. have taken over Staerker & Fischer's electrical business at 172, William-street Melbourne, and arrangements are being made to effect a similar transfer at an early date of their Sydney business to the company.

The general manager of the Australian Metal Co.'s electrical business will be Mr. J. M. Jolly, who filled a similar position with Staerker & Fischer.

Plant for Sale.—Elektron Limited (in liq.), Gothenburg, offer for sale triplo expansion engines, c.c. dynamos, &c. Further particulars are given in advertisements.

Messrs. Leo Sunderland & Co., 39, Victoria-street, Westminster, London, S.W., advertise for sale a 500 H.P. two-phase motor, liquid starter and regulator, two-panel switchboard, starting switch for barring motor, two 7½ kw. transformers and one 15 B.H.P. squirrel cage motor.

"The Journal."—Part 206 of the "Journal of the Institution of Electrical Engineers" is now ready, price 5s. Particulars of contents are given in an advertisement.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during April, 1911, and (*b*) during the current year from Jan. 1 to April 30, with the increases or decreases compared with the corresponding periods of 1910:—

Electrical machinery (*a*) £114,514 (increase £70,344), (*b*) £382,198 (increase £200,609); telegraph and telephone cables (*a*) £29,774 (increase £14,031), (*b*) £121,617 (increase £68,969); telegraph and telephone apparatus (*a*) £13,087 (decrease £3,808), (*b*) £52,031 (decrease £6,765); other electrical wires and cables, rubber insulated (*a*) £6,696 (decrease £6,291), (*b*) £30,435 (decrease £18,792); with other insulations (*a*) £1,985 (decrease £840), (*b*) £13,537 (increase £4,643); carbons (*a*) £8,983 (decrease £1,562), (*b*) £45,671 (decrease £620); glow lamps (*a*) £30,999 (decrease £1,987), (*b*) £116,207 (decrease £56,747); arc lamps and electric searchlights (*a*) £135 (increase £10), (*b*) £564 (decrease £837); parts of arc lamps and searchlights (other than carbons) (*a*) £6,728 (decrease £97), (*b*) £35,949 (increase £11,750); primary and secondary batteries (*a*) £2,554 (decrease £1,830), (*b*) £15,945 (increase £2,104). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £110,624 (decrease £1,717), (*b*) £468,174 (increase £7,456).

Exports.—The exports of electrical machinery, material, &c., (*a*) during April, 1911, and (*b*) during the current year from Jan. 1 to April 30, and the increases and decreases compared with the corresponding periods of 1910, are as follows:—

Electrical machinery (*a*) £104,265 (increase £40,472), (*b*) £541,975 (increase £79,477); telegraph and telephone cables (*a*) £44,683 (decrease £16,211), (*b*) £239,946 (decrease £564,190); telegraph and telephone apparatus (*a*) £24,744 (increase £7,618), (*b*) £94,349 (increase £41,869); other electrical wires and cables, rubber insulated (*a*) £33,189 (decrease £6,040), (*b*) £135,936 (decrease £1,490); with other insulations (*a*) £24,157 (decrease £8,286), (*b*) £132,297 (increase £53,166); carbons (*a*) £1,228 (decrease £384), (*b*) £6,804 (increase £614); glow lamps (*a*) £10,143 (increase £166), (*b*) £52,198 (increase £10,391); arc lamps and searchlights (*a*) £1,282 (decrease £672), (*b*) £5,813 (decrease £1,109); parts of arc lamps and searchlights (other than carbons) (*a*) £1,275 (increase £113), (*b*) £4,736 (increase £56); primary and secondary batteries (*a*) £18,292 (increase £11,091), (*b*) £50,024 (increase £16,454). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £205,358 (decrease £1,725), (*b*) £902,680 (decrease £415,399).

BANKRUPTCIES, LIQUIDATIONS, &c.

At a recent meeting of the creditors of Arthur Brooke, trading as Fox & Co., electrical engineers, Batley, the statement of affairs showed liabilities £917.

After deducting preferential claims £898 is expected to rank for dividend. Unsecured trade creditors represent £272, and there were two claims for money lent—£150 and £100. Assets estimated to produce £161, leaving deficiency £737. Mr. W. D. Burlinson, C.A., is trustee under a deed of arrangement, with a committee of inspection.

A meeting of creditors of the North-Western Electricity & Power Gas Synd. (Ltd.) is held to-day (May 12) at 37, Cross-street, Manchester.

First meeting of creditors of A. C. A. Wampach, electrical engineer, Formby Lodge, Seabrook-road, Hythe, May 17, at 68A, Castle-street, Canterbury; public examination on May 20 at the Guildhall, Canterbury.

A meeting to receive an account of the winding up of the Acme Patent Fire Alarm Co. (Ltd.) will be held on June 9 at Broad-street-chambers, Bristol.

A meeting to receive an account of the winding up of the British Radio-Telegraph & Telephone Co. (Ltd.) will be held on June 6 at 5, London Wall-buildings, London, E.C.

Cowans Limited is being wound up voluntarily. Claims to the liquidator, Mr. C. Cooper, 33, Princess-street, Manchester. Meeting of creditors will be held at 60, Spring-gardens, Manchester, on May 17.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Co. (Ltd.)

The seventy-ninth ordinary general meeting was held on Wednesday, under the presidency of Mr. GEORGE KEITH.

The SECRETARY (Mr. A. C. Austin) read the notice calling the meeting and the report of the auditors.

The CHAIRMAN said: The accounts show an exceptionally good result for the half-year under review, which is generally the slack season of the year. The traffics for the six months compare favourably with those for the corresponding months of 1909. The improvement shown may be attributed to the increased prosperity and more active state of business in Cuba and the West Indies. Cuba suffers more or less every year from storms, which, fortunately for our business, increase the use made of our cables along the south coast of the island. The cyclone last October did immense damage in the western portion of the island. Our cable house at Batabano was entirely wrecked, and the landline connection with Havana was interrupted for several days. The loss of traffic during that time, I am glad to say, was more than made good by the large increase after the communication had been restored, with the result that October now shows an increase instead of the loss we had anticipated. November compares well with the large increase produced by the hurricane of the preceding November, and altogether the traffic for the whole half-year shows a very satisfactory increase. Now, turning to the revenue account, the traffic receipts for the half-year show an increase of £1,876. Interest on investments and the deposit at the bank is £96 more. The gross revenue, including transfer fees, amounts to £18,351, or £1,975 more than it was in 1909. On the debit side of the account the London expenses are slightly less. Station expenses are £348 more, due to an additional item for cable repairs, which does not occur every year, and to a decrease in the aggregate of other items. Income tax is less. Law charges are less, while the other charges remain unaltered. Altogether the total working expenditure amounts to £6,672, or £257 more than it was in 1909. The result of the half-year's business is a balance of profit of £11,679, out of which £2,000 has been placed to the reserve against depreciation on investments, and £2,000 to the general reserve. After providing for the dividend on the preference shares, the directors now recommend the payment of the usual dividend at the rate of 6 per cent. per annum on the ordinary shares, free of income tax, reducing the balance carried forward by £121 to £7,275. I think we may consider the result of the half-year's business as satisfactory. We are in a position to meet the additional expenditure to be incurred in re-establishing duplicate direct communication between Cienfuegos and Santiago, so as to ensure the efficient transmission of the through traffic. At our meeting last October I took occasion to call your attention to this matter, and I have now the pleasure to inform you that a contract has been entered into with Hooper's Telegraph Works for the manufacture, transport and laying of the new cable required between Cienfuegos and Cape Cruz, where it will join the present cable to Santiago, and thus complete the duplication of direct communication between Havana and Santiago. The cable will be laid about the end of this year, when the weather conditions are most suitable for successfully carrying out the work. In conclusion, you will be pleased to see by the report that Mr. Scott still remains with us in a consulting capacity. He has been connected with the Company for 35 years, 32 of which he has been its secretary. During all these years he has been working strenuously in its interests, and its success has been greatly promoted by his energy and zeal. I am quite sure you will join me in thanking him for his past services, and in expressing the wish that the Company may long have the benefit of his experience and advice in the management of its affairs. I now move the adoption of the report and accounts.

Mr. CHARLES W. PARISH seconded the resolution, which was adopted. The dividends were approved, and a vote of thanks to the chairman, directors and staff brought the proceedings to a close.

Great Northern Telegraph Co. (Ltd.)

At the meeting, which was held at Copenhagen on April 29, the Chairman (Commodore E. Suenson, D.R.N.) gave an account of the working of the Company during 1910. He said the condition of their cables had been about normal. In Europe there had been 21 interruptions on 10 cables and in the Far East 15 on six cables. Cable repairs and renewals had kept their cable steamers occupied: the "H.C. Orsted" in Europe for 112 days, and the "Store Nordiske" and the "Pacific" in the Far East for 264 days, of which 8 in Europe and 65 in the Far East were for the account of other administrations. The landline routes viâ Kiachta and viâ Wladiwostock connecting their two submarine systems had

Digitized by Google

worked very satisfactorily, notwithstanding that on the former a number of telegraph poles were renewed last summer. The Chinese Administration took advantage of the opportunity to introduce a more effective inspection of the lines, which needed improvement. In the beginning of the year the landlines connecting the company's cables with the transmitting offices suffered considerably on account of the severe weather prevailing almost everywhere. In France the damage was due to the destructive inundations of the River Seine, whilst in England and Sweden snow-storms played great havoc with the lines, particularly during January and February, but thanks to the energetic measures taken by the respective administrations the transmission of the traffic suffered comparatively little delay. In previous reports shareholders had been advised of the decision of the Norwegian Government not to extend the company's concessions beyond 1910, and also of the desire of the Japanese Government to acquire the cable between Japan and Korea before the expiration of the concession in 1912. The past year witnessed the consummation of these decisions. The separation from Norway was solely due to the determination of the Government, whilst that from Korea was entirely voluntary on the part of the company. In fact, from the moment when Korea, on Aug. 22, 1910, was officially incorporated in the Japanese Empire under the name of Chosen, the company's Korean cable naturally became an integral link of the interior Japanese telegraph system. Without failing in their obligations or duties in other directions, the company had thus the opportunity of proving their readiness to meet the Imperial Government's desire by prematurely parting with the cable. The total payments for the cession of the three cables (the cables between Egersund, Norway, and Peterhead, Scotland, between Arendal, Norway, and Hirtshals, Denmark, and the Korean cable), with accessories (such as cable huts with furniture, instruments, &c.), and compensation for revenue of about two years on the Korean cable, amounted to approximately £32,000. This result was far from satisfactory, but they had never concealed from the shareholders that, on the expiration of the concessions, they were more or less at the mercy of the Governments, and they had, therefore, in their financial policy, always kept in mind that contingency. Whilst regretting the loss of the three cables, it had, on the other hand, given them great satisfaction that the British Government had entrusted the company with the working in the United Kingdom, on behalf of the General Post Office, not only of the Egersund–Peterhead cable, the service of which thus continued in the company's hands, but also of a new cable, laid in October and November last by the two Governments, between Newbiggin in England and Arendal in Norway. This arrangement would in no way reduce the financial losses resulting from the cession of the Egersund Peterhead cable, but it was a highly gratifying proof of the good feeling of the General Post Office towards the company and of their appreciation of the services which they had been rendering to the telegraphing public for more than 40 years. Furthermore, they were able to inform the shareholders that the British General Post Office had, jointly with the Norwegian Telegraph Administration, entrusted to the company the maintenance of the two Anglo-Norwegian Government cables mentioned, and that they had entered into a similar arrangement with the Norwegian and Danish Telegraph Administrations for repairing the Dano-Norwegian cable between Hirtshals and Arendal. We consider this a compliment to the company's engineering and cable repairing staff, who have, in fact, during a number of years, maintained the traditions of their ancient forefathers' maritime exploits—the memory of which is to be celebrated at the forthcoming festivities in Normandy—and they enjoy a well-merited reputation for their present achievements, both maritime and submarine, which happily have a more peaceful and useful object than those of their rough ancestors. The arrangements regarding the cables have been entered into provisionally for a term of five years. During the past year the company had also signed a new agreement with the General Post Office for working three of the company's other cables in Great Britain, for which the landing licences were prolonged in 1905. The old conditions had been only slightly varied, but, unfortunately, not to the company's advantage.

Unless an extraordinary increase of traffic should mitigate the loss caused by the transfer of the two Norwegian cables and the Korean cable, the company's telegraphic receipts would fall off considerably in the current year. The decrease would be further aggravated by the tariff reductions which they had had to introduce to maintain the equality of the rates working between the United Kingdom and the three Scandinavian countries before Jan. 1 last. The General Post Office and the Swedish Telegraph Administration had readily accepted the company's proposal for a similar reduction of the rates for the Anglo-Swedish and Anglo-Swiss traffic. The reduction of the first-mentioned rate had already come into force, but they were still awaiting the decision of the Danish Telegraph Administration as regards the reduction of the rate for traffic exchanged between the United Kingdom and Denmark. Reductions of rates had also been introduced between Sweden and Russia (Finland), as well as in the Far East, the company bearing a proportionate share. They had obtained the consent of the Telegraph Administrations of Russia and Sweden to lay a new cable (the fourth) between those countries which would soon be taken in hand, and they were also going to draw upon the reserve fund with the object of assisting the Chinese Telegraph Administration in their efforts to improve and extend the telegraph system of the Celestial Empire.

In spite of the inevitable decrease in traffic receipts from Jan. 1 last, they were satisfactory to report that for the past year the receipts had exceeded their expectations. Thanks to that and a small increase in revenue from other sources, and also, on the other hand, to an accidental decrease in expenses, the net revenue of 1910 had been about £23,400 higher than that of the previous year. That enabled them to maintain a total dividend of 18 per cent., and at the same time to carry forward a somewhat larger amount to meet the effects of the decrease of receipts which they anticipated during the present year. The usual amount has been transferred to reserve, while the contribution to the pension fund had been increased by one-third, in view of a corresponding increase in the number members of the fund since 1904, when the last increased contribution was granted. The board had provisionally requested His Exc. P. Lovenorn, late Danish Minister at St. Petersburg, to fill the place left vacant by the death, in February last, of Mr. P. Vedel. Traffic receipts had increased in round figures by £16,920, and interest and sundries by about £3,360, whilst expenses showed a decrease of about £3,000.

EASTERN TELEGRAPH CO. (LTD.)—The report of the directors for the half-year to Dec. 31 last states that the revenue for the period amounted to £670,147. 15s. 5d., from which are deducted £219,231. 0s. 9d. for ordinary expenses and £45,558. 10s. 7d. for expenditure relating to maintenance of cables, sundry differences in exchange, and income tax payable abroad, leaving a balance of £405,358. 4s. 1d., to which is added £59,590. 7s. 1d. brought from preceding account, making a total available balance of £464,948. 11s. 2d. After providing for income tax payable in England, interest on mortgage debenture stock and dividends on the preference stock, which in all absorb £81,186. 1s. 4d., there remains a balance of £383,762. 9s. 10d., out of which the directors have placed £180,000 to general reserve and have paid an interim dividend of 1¼ per cent. on the ordinary stock, amounting to £50,000. The directors now recommend the declaration of a final dividend on the ordinary stock of 1¼ per cent. and a bonus of 2 per cent., amounting together to £130,000, both payable on May 17, free of tax, and making, with the three previous payments on account, a total distribution of 7 per cent. for the year ended Dec. 31, 1910. It is proposed to carry forward the balance of £23,762. 9s. 10d. to next account.

The register of transfers is closed from 10th to 17th inst.

EASTERN EXTENSION AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.)—The directors' report just issued states that for the half-year ended Dec. 31 the gross receipts amounted to £336,976. 6s. 5d., against £315,034. 18s. 7d. for the corresponding half of 1909. Working expenses, including £22,607. 10s. 6d. for maintenance of cables, absorbed £154,300. 7s. 2d. against £143,674. 0s. 4d., leaving £182,675. 19s. 3d. From this is deducted £2,355. 11s. 2d. for income tax payable in England, £417. 14s. 6d. for extraordinary expenses and £15,048 for interest on debenture stock, leaving as net profit for the half-year £164,854. 13s. 7d. Adding £72,763. 5s. 11d. brought forward, the available balance is £237,617. 19s. 6d. One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on 17th inst., making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for 1910; £75,000 has been transferred to general reserve and the balance of £27,617. 19s. 6d. carried forward. An agreement has been entered into by the Imperial Chinese Government with the Eastern Extension and Great Northern Telegraph Companies for an advance to the Board of Communications of £500,000 at 5 per cent. interest on account of the monies payable by the Companies to the Imperial Chinese Telegraph Administration under their existing agreements. The advance has been obtained to enable the Board of Communications to reorganise, improve and develop the telegraph and telephone services throughout the Chinese Empire. The wireless telegraph installation referred to at the last meeting as then in course of erection at the Company's Keeling-Cocos station, to enable telegrams to be exchanged between passing ships and that remote place, was opened for public service on March 2 last. The negotiations with the British Government for extending the wireless service to the Company's Singapore, Hongkong and other stations are proceeding.

The register of transfers is closed from 9th to 16th inst.

SUBMARINE CABLES TAUST.—The revenue for the year ended April 15 amounted to £25,205.10s. and the expenses to £1,172. 6s. 7d., leaving £24,033. 3s. 5d., to which is added £175. 4s. 11d. brought forward, making £24,208. 8s. 4d. After providing £17,583 to meet payment of coupons, £6,578. 13s. has been transferred to redemption fund, leaving £46. 15s. 4d. to be carried forward. Since the last report, in accordance with the terms of the trust deed, 55 certificates (exclusive of coupons of reversion) have been redeemed, absorbing £6,578. 13s.; of these, 34 were purchased in the open market during the year, and 21 were drawn by lot on 4th inst. By a resolution of the trustees, £15,850 Anglo-American Telegraph Co.'s preferred stock has been sold and the proceeds invested in shares of the Great Northern and Western Telegraph Companies.

WEST AFRICAN TELEGRAPH CO. (LTD.)—The directors' report for the year ended Dec. 31 states that the revenue amounted to £61,797. 2s. 9d. and ordinary expenses to £15,602. 10s. 9d. £5,320. 19s. 1d. was required for expenditure on maintenance of cables and income tax abroad, leaving £40,873. 12s. 11d., with £922. 7s. 8d. brought forward, the available balance was £41,796. 0s. 7d. £1,139. 5s. 8d. has been provided for income tax, £31,000 transferred to general reserve and an interim dividend of 2 per cent. (tax free), absorbing £4,621. 16s., was paid on Dec. 1, last. The directors recommend a final dividend of 2 per cent. (tax free), making 4 per cent. for the year, £233. 2s. 11d. being carried forward.

WEST COAST OF AMERICA TELEGRAPH CO. (LTD.)—The report of the directors for the year ended Dec. 31, 1910, states that the gross receipts amounted to £51,216. 16s. 7d., against £50,416. 6s. 11d. in 1909. Working expenses were £39,356. 19s. 7d., compared with £39,204. 13s. 7d.

Digitized by Google

After providing £6,000 for interest on the 4 per cent. debentures, £800 for interest on the 4 per cent. income bonds and £267. 2s. 10d. for income tax, there remains £4,792. 14s. 2d., added to £613. 14s. 5d. brought forward, making together £5,406. 8s. 7d. Of this £1,000 has been placed to general reserve and the directors recommend a dividend of 2½ per cent. (tax free), amounting to £2,813, leaving £1,593. 8s. 7d. to be carried forward.

WEST INDIA & PANAMA TELEGRAPH CO. (LTD.)—The directors' report for the half-year ended Dec. 31, 1910, states that the amount to credit of revenue is £40,306. 9s. 5d., against £34,678. 12s. 1d. for the corresponding half-year of 1909. Expenses have been £24,319. 0s. 6d., against £23,557. 18s. 6d. The balance is £15,987. 8s. 11d., to which is added £1,599. 1s. 4d. interest and £1,953. 5s. 10d. brought forward, making an available total of £19,539. 16s. 1d. The directors propose to pay the first and second preference dividends of 6s. per share to Dec. 30, and a dividend of 1s. 6d. per share (tax free) on the ordinary shares, carrying forward £1,146. 2s. 7d. Traffic receipts for the six months show an increase of £5,645. 1s. compared with the corresponding period. At the meeting on 17th inst Mr. Robert Jackson (a shareholder) will propose a resolution that £600 be voted to the directors in recognition of their past services to the company.

WESTERN TELEGRAPH CO. (LTD.)—The report of the directors for the half-year ended Dec. 31 states that the revenue amounted to £431,966. 16s. and working expenses to £162,753. 4s. 8d. After providing £16,373. 10s. for debenture stock interest, and £7,697. 9s. 10d. for income tax, the balance is £245,142. 11s. 6d., added to £7,512. 18s. 8d. brought forward making £252,655. 10s. 2d. First and second interim dividends (amounting to £62,379) have been paid, and after transferring £150,000 to general reserve and £10,000 to land and buildings depreciation fund, there remains £30,276. 10s. 2d., which is carried forward.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c,

NEW COMPANIES.

ARON TAXIMETER (LTD.) (115,599.)—Reg. March 3, capital £5,000 in £1 shares, to carry on the business of manufacturers and contractors for the sale, erection and maintenance of taximeters, speedmeters, electricity and other meters, electric lamps, electrical switches and cut-outs, and other electrical apparatus, &c. Private company. First directors: M. Aron and Dr. J. Juttke. Reg. office: 80A, Salisbury-road, Kilburn, London, N.W.

BAXTER & CAUNTER (LTD.) (115,516.)—Reg. April 29, capital £50,000 in £1 shares, to take over the business of electrical engineers carried on as Baxter & Caunter, and to adopt an agreement with A. Baxter, L. G. Caunter and G. W. Kettlewell. Private company. First directors, A. Baxter, L. G. Caunter and G. W. Kettlewell (all permanent). Reg. office: 1, Trentishoe Mansions, Charing Cross-road, London, W.C.

BUCKMAN FOREIGN PATENTS SYND. (LTD.) (115,553.)—Reg. May 1 capital £1,000 in £25 shares, to carry on the business of engineers, manufacturers of, dealers in and contractors for all kinds of engines, motors, dynamos, machinery and mechanical, or electric or scientific appliances, &c., and to adopt an agreement with R. S. Buckman. Private company. First directors: N. B. Dickson, C. F. Leighton and F. McLure. Reg. office: 2, Clements Inn, Strand, London, W.C.

CHARLEVILLE ELECTRIC CO. (LTD.) (3678).—Reg. April 27, capital £2,000 in £1 shares, to manufacture, buy, sell and deal in electricity for light and power. First directors: J. R. Daly, J. Morrissey, W. P. Binchy, M. J. O'Mahony, J. Carroll, J. R. O'Connor and J. P. Moran.

ELECTRICAL FITTINGS CO. (1911) (LTD.) (115,433).—Reg. April 25, capital £5,000 in £1 shares, to take over the business of electric engineers and fitters, and manufacturers and sellers of electrical fittings carried on as the Electrical Fittings Co. (Ltd.), and to adopt an agreement with W. K. Sutton and A. W. Mills. Private company. First directors: A. W. Mills (permanent). W. K. Sutton, F. Rowe and W. Towell. Reg. office: 38, Conduit-street, London, W.

SOUTH EAST KENT ELECTRIC POWER CO. (LTD.) (115,633.)—Reg. May 4, capital £1,000 in £1 shares, to carry on the business of electrical engineers, electricians, contractors, manufacturers of electrical apparatus, suppliers of electricity, &c. First directors, A. Burr, M. Burr, D.Sc., and Sir W. H. Crundall, Kt., J.P. Reg. office: Castle Hill House, Dover.

TELEPHONE DEVELOPMENT CO. (LTD.) (115,661.)—Reg. NOTES.

Tramway Fares.

In the case of a municipally controlled tramway undertaking the question of fares frequently produces a considerable diversity of opinion between the various members of the Council. Indeed, it is almost inevitable that such should be the case, since the opinion of individual councillors on this question is certain to be affected to some extent by the desirability of pleasing different sections of the ratepayers. During recent years the desire to popularise their tramways has led some committees to grant exceptional facilities for cheap travelling, such as half-penny fares, which the majority of tramway managers believe are unreasonable except under very exceptional circumstances. There has also been a growing tendency to introduce still cheaper (and more unprofitable) fares for workpeople and others travelling before a certain hour in the morning, on the assumption that the ordinary passenger traffic during the remainder of the day will counteract any loss that may result from the cheaper fares. If the effect of introducing such fares were to improve the "load factor" of the system, something might be urged in their favour, but in the majority of cases passengers obtaining such cheap tickets may return at the "peak" of the evening load at the low fare. The case, therefore, is very different from that of low-priced units in electricity supply.

Mr. J. M. McElroy, general manager of the Manchester Corporation Tramways, has recently presented to his Committee a very interesting report in regard to workpeople's fares. This Report deals with a proposal to extend from 7 a.m. to 8:30 a.m. the time during which such fares are in operation, and the Committee, after considering the Report, wisely decided not to make any further concession in this direction. In previous reports Mr. McElroy has pointed out that preferential treatment as regards fares tends to introduce difficulties, and he again emphasises the fact that the wisest policy for his Committee to adopt is to reduce the ordinary fares as low as is feasible, having regard to the financial stability of the undertaking, and to make everybody pay alike. This policy will certainly find many adherents. From a comparative statement accompanying the Report we notice that of 10 municipal tramway undertakings recording an "ordinary" fare per mile of ½d. or less, six (including Sheffield, Liverpool, Glasgow, and Leicester) have no workmen's fares in operation; the benefit of low fares, therefore, is in such cases more widely distributed. Although the Manchester and other large tramway undertakings record each year a very considerable surplus, it must always be borne in mind that the excess of income over expenditure is very small when reckoned per passenger. Thus, this margin is only $\frac{1}{10}$d. at Manchester, so that it obviously behoves even large successful tramway undertakings to pay great attention to any slight tendency for the average fare per passenger to decrease. That tramway revenue has not of recent years increased in accordance with general expectations is admitted, and it is noteworthy that a word of warning as to the possible necessity of increased fares owing to the tendency for the receipts per car-

Digitized by Google

mile to decline, was recently uttered by the Chairman of the Highways Committee of the London County Council.

Electric Supply Progress at Leeds.

In commenting in recent years on the progress made by the Leeds Corporation Electric Lighting Department we have referred to the decline in revenue from lighting consumers since the advent of the metal filament lamp, and we have expressed the opinion that the temporary decrease in the output would soon be arrested. Although that desirable position has not yet been quite reached, it is evident from a statement presented with the revenue account at the meeting of the Tramways and Electricity Committee this week, that the lowest point of the depression can now be gauged, if it has not already been passed. The sales of energy for private lighting for the 12 months ended March 31st last were, as a matter of fact, only 2·5 per cent. less than in the previous year, when a decrease of 12·7 per cent. was recorded. On the other hand, the output for power and heating shows an increase of over 30 per cent., and the total revenue from all sources an increase of £4,500. As working expenses only amounted to £795 more than last year, in spite of an increased output of about two million units, the result of the year's working is on the whole satisfactory, a surplus of almost £10,000 being shown. The gas journals can scarcely say, in the case of the Leeds electricity undertaking, that the cheap power supply is provided at the expense of the lighting consumers; indeed, as the output for power and heating is now more than twice that for private lighting, and is increasing at a rapid rate, the lighting output will soon become a comparatively unimportant factor. This result is the more gratifying in that the undertaking has not the benefit of a tramway load; and when this is borne in mind, the low cost per unit sold reflects the greatest credit on the engineer and manager, Mr. H. Dickinson. The fuel figure last year of 0·17d. per unit sold, which was one of the lowest recorded in this country, has on the present occasion been reduced to 0·15d. per unit, so that other undertakings have now a still more difficult task in attaining the high level of efficiency set them by Leeds.

Burton-upon-Trent.

We have always examined with interest the annual report and balance-sheet of the Burton-upon-Trent Electricity Department, and those which have come to hand this week show a very satisfactory state of affairs. Here the adverse effect of metal lamps has now passed, and in place of diminishing sales for lighting, it is very gratifying to record an increase of 7·4 per cent. for private lighting as compared with last year's output. As the number of units sold for power has increased by over 27 per cent., it is not surprising that the surplus shown in the accounts is the highest yet recorded. In view of this fact, the Council have probably felt justified in appropriating £1,000 for the relief of rates. It is interesting to notice that although meters were only installed on the tramcars towards the end of the year the consumption of energy has declined by 4·1 per cent., so that a much larger diminution in the output for traction is anticipated next year. The total cost per unit (excluding capital charges) of 0·92d. recorded last year (which is not high for a small undertaking) has on the present occasion been reduced to 0·81d., so that the economies introduced by Mr. P. J. Pringle are evidently being emphasised by his successor. That Mr. Pringle is no longer connected with the undertaking is apparent from the fact that neither in the report nor in the detailed statistics of the undertaking is any mention made of restricted-hour supply.

The Coronation Exhibition.

The Exhibition at Shepherd's Bush has now become an annual feature of London's entertainments. Although in the past the educational side of the Exhibition has by no means been sacrificed to the lighter forms of entertainment, the Science Section has not been as prominent as it might have been; in the Coronation Exhibition, however, which was opened yesterday by H.R.H. Prince Arthur of Connaught, this Section will certainly be a marked feature. On the present occasion an effort has been made to render the Section more attractive, and with this aim in view demonstrations are to be given. In the past, exhibits of scientific apparatus have had a tendency to become merely a collection of instruments of historic interest; but although the historical side of the present Science Section will be represented by the early apparatus used by Faraday, Wheatstone and others, modern apparatus and investigation will be much in evidence. Thus, models illustrating the application of electricity to agriculture have been loaned by the University of Bristol; whilst the indiarubber testing machine of Prof. Schwartz, electric resistance furnaces, thermo-electric and Féry radiation pyrometers, vibration galvanometers, Dr. Drysdale's polyphase wattmeter and alternating-current potentiometer, &c., and other apparatus of which mention cannot be made here, are all in evidence. An experiment is also being arranged to show the negative coefficient of expansion of invar over a certain temperature range, whilst two dark rooms will enable stroboscopic methods of measuring speed and experiments with X-ray and vacuum tubes to be demonstrated. We may also draw attention to the fact that a special effort has been made to make the telegraphic and telephonic part of the Section of particular interest. With this object a syphon recorder working on an artificial Atlantic cable is shown whereby difficulties in transmission due to the effect of capacity can be illustrated. Again, the Marconi stations placed at either end of one of the halls will doubtless prove a centre of attraction, since the public will be able to transmit from one station to the other and see the actual operation of the apparatus. As regards the Exhibition itself, this is likely to prove as attractive as ever.

The New I.E.E. Wiring Rules.—A new rule, to which we omitted to draw attention in our article last week, and which is of some importance, is Rule 51 relating to "Open Wiring Armoured Conductors." This states that conductors (except flexibles) efficiently armoured with steel armouring or covered with brass, copper, or equally hard metal, may be used without conduits or wood casing. The armouring or casing must be connected to earth. This rule has doubtless been framed to meet the extending use of unprotected armoured conductors of which "Stannos" wires are typical.

Electricity Supply in Germany.—An article dealing with this subject by Mr. Meyer Coschütz appears in a recent issue of the "Elektrotechnische Zeitschrift." The author states that the change which has converted Germany from an agricultural into an industrial country has been accompanied by a rapid extension of the uses of electricity. Practically all towns of over 20,000 inhabitants are provided with electricity supply stations, and much attention is now being paid to various schemes for linking up rural districts. On the other hand, gas interests are very active, and the employment of gas has been considerably extended in places where the rates for electricity are high or complicated. The author considers that cheap and reliable electric cooking apparatus should be developed and the rates for energy used for this purpose reduced. To permit the electric light to be used by small consumers a flat rate should be charged.

Printing Telegraphy.—*Erratum.*—We regret that a slight error crept into our account of Major W. A. J. O'Meara's remarks on Mr. D. Murray's recent Institution Paper. On p. 168 of our last issue the word "feature" in the ninth line of Major O'Meara's remarks should be "feeder," the sentence, therefore, reading: "He (the speaker) entirely agreed that the telephone in the future would be a feeder of the telegraph system."

Entertainment by Long-Distance Telephone.—The "Electrical World" mentions that Mr. V. N. Bethell, president of the New York Telephone Co., entertained the Cliff Dwellers Club at his home in Montclair, N.J., on April 10, by means of speeches, music and recitations which came over the long-distance telephone from points in some cases thousands of miles distant. Performers were stationed at New York, Boston, Asbury Park, Washington, D. C., Detroit, Chicago and Denver. From Chicago Mr. W. D. Nesbit made a regular after-dinner speech, and from Detroit Mr. A. S. Hibbard, of the Chicago Telephone Co., sang a song. The feature by the fifteen participant was a reading which came over the wires a distance of about 2,000 miles with perfect clearness. The talking from Denver was over a phantom circuit made up of two pairs of copper No. 8 wires. The event was one of great interest to Mr. Bethell's guests, and was an exceptional demonstration of the comparative perfection now achieved by long-distance telephony.

An Interesting Generating Set.—"A rapidly increasing tendency," says the "Electrical Review and Western Electrician," towards combining auxiliary apparatus as much as possible in fewer sets of independent units is exemplified by a turbine set recently installed at the Easthampton cotton mills of the West Boylston Mfg. Co. This set consists of a 100-volt Behl generator furnishing direct current at 100 volts. The generator is direct driven by a 75 H.P. Terry steam turbine at 1,750 revs. per min. Beyond the generator, and mounted on the same bedplate with both the latter and the turbine, is an 8-in. centrifugal double-suction pump, which may be disconnected by means of a flexible coupling joining the generator and pump shafts. By operating the turbine 24 hours a day it is possible to obtain three different classes of service from this unit. Throughout the winter the pump, which has a capacity of 150 gallons per minute, furnished the hot water for heating the mill. The generator during the day is connected to the main bus bars for the main units which generate power for operation of the mill, and during the night it is switched over to the lighting circuit, so that it has approximately a 100 per cent. load factor. During the summer the pump is idle. Even the uses of the exhaust steam from the turbine vary at different seasons. During cold weather it is used for heating the water of the mill-heating system, while in warm weather it is changed over to the boiler feed-water-heater line."

Cable Interruptions.

	Date of Interruption.

Electric Wiring and Lighting Equipment of Boston Stock Exchange.—According to the "Electrical World," a new board room is rapidly approaching completion for the Boston Stock Exchange, and electricity will play a prominent part in its service. Fifty-two telephone booths equipped with private wires have been installed, and an elaborate telautograph, telegraph, electric fan and lighting installation is also to be maintained. Although the wiring is concealed, there is to be easy access to every cable through concealed closets in the pillars which carry the principal circuits. The quotation boards are to be equipped for magnetic operation. In place of the present card racks the boards will be provided with magnetised surfaces, against which the board boys will place tin cards with iron backs. It is expected that much time will be saved by this arrangement. Elaborate provision is to be made for artificial electric ventilation and lighting, although the building is designed with a large glass dome, which will render the use of natural light much more common than in the present quarters of the Exchange.

"The Electrician"—Second Mining Issue.—*Errata.*—We regret that owing to the great pressure of work attendant on the preparation of this issue one or two errors have crept in. In the article on "Electric Winding in Collieries" Messrs. Crompton & Co. point out that the curve shown in Fig. 7 on p. 130 is likely to be misunderstood. The current and voltage curves refer to the secondary circuit of the motor generator and not to the main current. The current taken from the supply mains is not given, but it starts at a small value and assumes approximately the form of the kilowatt curve in the diagram. In the article on Messrs. Siemens' high-tension telephone on p. 181, Fig. 1 is a watertight mining telephone, the high-tension telephone with the protective apparatus being shown in Fig. 2. Fig. 4 is a diagram of the protective devices only and not of the telephone. We also regret that owing to extreme pressure on our space some interesting illustrations had to be omitted from the article on "The Phœnix Flame-Proof Motor." In the article on "Liquid Starters and Controllers," on p. 161 it should have been stated that Mr. T. R. H. Tetley's works are at Salford, not Leeds.

The Reliability of Tramway Service.—An indication of the efficiency of the tramcar operation in the New York metropolitan district is afforded by the monthly comparative reports of car defects, published by the Public Service Commission of First District and abstracted in the "Electrical World." The report for February shows that not one of the seven systems compared suffered through defects in car equipment more than 0·85 times per 1,000 car-miles operated, while one of them had only 0·17 times per 1,000 car-miles. A study of the figures brings out strongly the superior reliability of the overhead trolley over the conduit plough collector which the railways in Manhattan Borough are compelled to use. Thus 53·27 per cent. of the car defects reported by one conduit railway were due to ploughs alone, whereas the corresponding maximum of overhead current collector troubles was only 3·03 per cent. If the conduit railways had been operated by the overhead system their records would have approached, if not bettered, those of their fellow companies. Other items show wide differences. Thus motor troubles vary from 13·42 per cent. to 51·25 per cent., and car body troubles from 2·78 per cent. to 24·79 per cent. Of course, the widely different conditions of service have much to do with these variations. Taken all in all, our contemporary remarks, the small ratios of interruptions show what can be accomplished by a thorough going maintenance policy even in densely populated cities and in congested streets where the conditions of street railway operations are very arduous.

Trimming and Inspection of Arc Lamps in Philadelphia.—According to the "Electrical World," the trimming of the lamps on the newly-erected twin lamp poles in the centre of Philadelphia was a problem which was not solved until several arrangements had been considered. Finally, an electrically-driven tower waggon which could be operated from the upper platform was designed. This vehicle, weighing about

Digitized by Google

3,250 lb., 2,600 lb. of which is due to the battery, is equipped with a 42-cell battery. This is sufficient to drive the waggon at 15 miles per hour on the level with a range of about 30 miles. The controller is mounted on the upper platform, and can be operated from either the upper or lower seat by a tube outside the steering shaft. The reversing mechanism is a Z-slot bushing keyed on the controller tube, which is worked from the upper seat by the foot and from the lower seat by the hand. The steering gear is mounted in the usual manner, and is worked from the upper or lower seat by a shaft which runs through the controller. The brakes can be worked from the lower seat by a foot lever in the usual manner and from the upper seat by a foot-lever, rod and crank. The upper foot lever has an extension, so that the operator can set the brakes from the top seat, climb down and release the brakes from the lower seat, or vice versa. The electric bell is operated from either the upper or lower seat by a floor push in the footboard. The platform is 13 ft. 6 in. from the ground, and an additional height can be secured by hanging a portable stand from the side rails, which will increase the height to either 14 ft. or 15 ft. 6 in., depending on which rail is used. This waggon enables a man to make his round in six instead of nine hours. The waggon is also used for inspection purposes at night, while the sentences "Use electric power" and "Use electric light," which are painted on its sides, give it some utility as an advertising medium.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. A. P. Trotter contributes an article on "The Nomenclature of Primary and Secondary Sources of Light."

Mr. D. C. M. Hume contributes an article on "The Electrical Equipment of a Modern Theatre."

Mr. A. Duckham contributes an article on "Transformer Oil."

At the meeting of the Institution of Electrical Engineers last night Mr. W. Aitken read a Paper on "Automatic Telephone Exchange Systems."

We give an account of the discussion that took place at the meeting of the Institution last week on Mr. H. J. S. Heather's Paper on "The Driving of Winding Engines by Induction Motors."

We also give an abstract of Mr. J. H. Reynolds' Paper on "Higher Technical Instruction," read at the recent Imperial Education Conference.

We give an abstract of a Paper by Mr. W. R. Cooper on "The Benkö Primary Battery and its Applications," accepted by the Institution of Electrical Engineers. The revival of the Primary Battery is discussed in our Leading Article.

This week has been notable for the annual meetings of a number of the leading submarine telegraph companies. The keynote of the chairmen of these meetings is the generally satisfactory trade outlook, the necessity for maintaining large reserve funds to meet probable capital requirements in the way of strengthening existing and laying new cables, and maintaining the stability of submarine telegraph stocks as a safe and reliable investment. The loyalty and efficiency of the staffs of the companies at home and abroad has received strong recognition on all hands.

The Coronation Exhibition at Shepherd's Bush was opened yesterday. We give a brief account of the exhibits of electrical interest in the Science Section, which is to be a more prominent feature than in the past.

Norwich Corporation have appointed a special committee to report upon the offer of the local tramways company to sell their undertaking to the Corporation.

Municipal Loans.—A Local Government Board inquiry was held last week at South Shields into the application of the Council for sanction to borrow £8,960 for additional plant, &c. The application was opposed by the local dock company, who wanted a supply of three-phase energy which they alleged could not be given by the Corporation.

An inquiry was also held at Rotherham into the application of the Corporation for permission to borrow money for extension of their electricity undertaking.

Parliamentary.—A Select Committee of the House of Lords have rejected the Matlock Rail-less Traction Bill and have decided to allow the Brighton, Hove & District Rail-less Traction Bill to proceed. The Malvern Bill, seeking similar powers, was withdrawn. The same Committee have this week been considering the Bill of Aberdare Urban Council for tramway and rail-less traction powers.

PERSONAL NOTES.

Mr. J. J. Steinitz is resigning his position as joint general manager of the Brush Electrical Engineering Co. to take up the post of general manager of the Gloucester Railway and Carriage Works, a change which will be to his material advantage. Mr. Steinitz is to be congratulated both on his new appointment, and on the fact that he only leaves the Brush Co. when it has reached a much improved position.

Mr. Dyer, shift engineer to the Barnes electricity undertaking, has resigned, in order to take up a position at Zanzibar.

APPOINTMENTS VACANT AND FILLED.

A telegraph inspector is required for the Bauchie Light Railway, in Northern Nigeria, for two tours, each of 12 months residential service. Salary £250, rising to £300 per annum by annual increments of £10. Applications at once to the Crown Agents for the Colonies, Whitehall-gardens, London, S.W. See an advertisement.

The Allmanna Svenska Aktienbolaget, Västerås, Sweden, require for their estimating department an electrical engineer with large experience in working out estimates for electrical schemes. See an advertisement.

The Electric Construction Co. advertise for a test bed assistant, experienced in testing all kinds of a.c and d.c. dynamos and motors.

A professor of chemistry is required for the University of Otago, Dunedin, N.Z., Salary £600. Particulars fron the High Commissioner for New Zealand, 13, Victoria-street, London, S.W., to whom applications by June 1.

A lecturer is required in the engineering department of the Borough Polytechnic Institute, Borough-road, S.E. Salary £150 to £180 rising to £250. Applications by May 24.

The Yorkshire Electric Power Co. advertise for a superintendent to undertake the control of the department engaged in laying underground and overhead mains, equipment of sub-stations, &c. Salary £250 per annum. Applications to the Company, Thornhill, Dewsbury

Messrs. Mather & Platt, Park Works, Manchester, are advertising for an engineer conversant with all details of the application of electricity to collieries, and paper and textile mills.

Messrs. Hazell, Watson & Viney (Ltd.) advertise for an electrician for their famous printing factory at Aylesbury.

Mr. S. H. Penning, distribution engineer at Woolwich, has been promoted to the position of assistant borough electrical engineer.

INSTITUTIONS AND SOCIETIES.

Institute of Metals.—On Friday last Dr. G. T. Beilby, F.R.S., delivered before the Institute of Metals a lecture on "The Hard and Soft States in Metals." He said that the hardening effect of cold working on ductile metals, and the softening effect of re-heating must have been known to the earliest workers in metals. To the inquiring mind, the phenomena were sufficiently explained as being due to the "compacting" effect of hammering and the "opening up" effect of heat. The advent of more scientific methods of inquiry led to the exposure of this fallacy, and to the discovery of new points of difference in a metal in the two states. The discovery that the polishing of all substances, even of those so hard or brittle as antimony or calcspar, involved the transient liquefaction of a thin layer on the surface, led to the study of this subject from an entirely new point of view. In a pure ductile metal, slowly cooled from the molten state, the structure of the solid was completely crystalline and the metal was in its softest condition. Any permanent deformation of the mass, whether by hammering, by rolling or by wire drawing, hardened and stiffened it. The microscopic examination of the hardened metal showed that its original crystalline structure had been broken up and replaced by a new type of structure. If the hardened metal were raised to a sufficient temperature the softness was completely restored and the crystalline structure was also restored. In the ductile metals the greatest degree of softness was always associated with well-developed crystallisation. The composite character of the hardened structure, which in some cases resembled a bed of broken and distorted strata concreted or cemen

Digitized by Google

together by a matrix, could only be explained by the presence of two constituents, namely, the broken-down remains of crystals and an amorphous or glass-like form of the metal by which the mass was so firmly cemented together that it had become vastly more rigid and mechanically stable than the crystalline structure. This amorphous or vitreous form of the metal stood in the same relation to the crystalline form as glass did to the crystalline silicates of which it was composed, or as the clear vitreous "barley sugar" did to the ordinary crystals of the breakfast table. The pure ductile metals could not be obtained in the vitreous state by cooling because their molecules retained sufficient mobility to enable them to marshal themselves in crystalline formation for a range of about 800 deg. below the solidifying point. All the facts showed, however, that when deformation was produced by mechanically-induced flow, the solidification was so rapid that the solid which resulted was in the vitreous condition. The direct bearing of these researches on the obscure subject of molecular structure in solids was pointed out, and a "pulsation cell" hypothesis of the three states of matter was outlined. Prof. Quincke's "foam-cell" theory of solidification was referred to and was applied to the explanation of certain observations made by Prof. Carpenter some years ago. In view of the possible bearing of this theory on questions of foundry practice, it was suggested that the Institute of Metals might offer a prize for the best research on the subject.

Students' Section of the Institution of Electrical Engineers.—In the annual report of this section for the session 1910-1911 it is stated that there have been 10 meetings, the average attendance at which was 82. In addition to these, the Manchester students have held 5 meetings and the Glasgow students four meetings. The opening address was delivered by Mr. C. H. Wordingham, on "The Training of an Engineer," and eight other Papers were read and discussed. The quality of the discussions shows continual improvement, the average number taking part being eight. The committee is of opinion that this result, as well as the large increase in attendance, is to a large extent due to the fact that copies of the synopsis of each Paper have been sent to those members who attend regularly. The committee feels that even better results could be obtained by the provision of a printed abstract. There have been 14 meetings of the Committee, and sub-committees have been appointed to deal with various matters. A tour was arranged to take place in July, 1910, to visit works in the neighbourhood of Birmingham, but the visits were very poorly attended. A tour is being arranged for the summer of 1911 to visit places of engineering interest in Sweden. A preliminary circular has already been issued, and further particulars are now in preparation. Considerable correspondence has taken place between the Students' Committee and the local branches of the Students' Section at Manchester and Glasgow, the subject being the necessity for some alteration in the constitution of the Students' Section, especially in the relation between the Students' Committee, which sits in London, and the Local Students' Committees which sit at Manchester and Glasgow. Correspondence on this subject has also taken place between the Local Students' Committees and the Secretary of the Institution. The whole subject of the constitution of the Students' Section is now under the consideration of the Council. In presenting this report, the committee wishes to place on record its appreciation of the comfort and advantages afforded by the new premises. The committee feels that the improvement in the interest shown in the Students' Section is in no small measure due to these facilities, and expresses the hope that these improvements will continue.

Society of Engineers.—The annual dinner of this Society will be held at the Criterion Restaurant, on Saturday the 27th inst., at 6:30 p.m. Mr. F. G. Bloyd, the President, will be in the chair, and the guests will include Mr. Alex. Siemens, President of the Institution of Civil Engineers, Mr. E. B. Ellington, President of the Institution of Mechanical Engineers, Prof. C. V. Boys, F.R.S., Sir [illegible], F.R.S., and others.

Scottish Section of the Institution of Electrical Engineers.—The annual report of this section states that the past session has been remarkable by a large accession to their membership and by change of organisation. The suggestion by members of the Institution in Edinburgh and district that they should join the Glasgow Section, and that it should assume a title of wider territorial significance was cordially received by this committee. The further proposal to incorporate in this local section all the members of the Institution resident in Scotland was submitted by referendum to the whole of the members, and having obtained an almost unanimously favourable response, it was referred to and approved by the Council of the Institution, which also approved "The Scottish Local Section of the Institution of Electrical Engineers" as the new designation of the section. The Council of the Institution hopes, the report continues, and the committee believes, that the expansion of this local section which has been accomplished will benefit the whole Scottish membership and extend the usefulness and influence of the institution in Scotland. The Institution is the only one among the great scientific institutions of the country which provides the advantages of local section organisations to provincial members, and the greater the distance from the central institution the more pronounced are the advantages of local sections to the members concerned. The report shows that six meetings were held during the session, one being cancelled owing to the death of Mr. J. R. Barr. An annual dinner and a steamer excursion also took place. The membership has increased by 51 during the past session. The report concludes: "The committee during the past session has, through the chairman, had communications with the Council of the Institution regarding a number of matters affecting the local sections. The chief object of these was the closer relationship of the local sections, and specially of this section, with the corporate life of the institution. It was felt that in the past the arrangements as to the representation of this section on the Council in London did not fulfil their purpose of enabling us to take a useful part in the conduct of the affairs of the Institution, and our section has, so far as the deliberations of the Council in London are concerned, been in a position of isolation. Proposals relating to facilitating the attendance of local section representatives at the meetings of Council in London, and to other matters which your committee raised, were submitted to a specially arranged conference of the whole Council in London, to which the chairmen and hon. secretaries of all the local sections were invited. It is pleasant to record that all the proposals of the local sections were treated in the most sympathetic and considerate manner, and, subject to the interests of the institution as a whole, with the evident desire to remove such difficulties as the local sections have experienced. It is expected that the recommendations of the conference will be dealt with by the Council at an early date, after which fuller information will be communicated."

EDUCATIONAL NOTICE.

University of London.—A course of five advanced lectures on "The Application of Hyperbolic Functions to Electrical Engineering Problems," by Dr. A. E. Kennelly (of Harvard University), will be delivered in the Lecture Theatre of the Institution of Electrical Engineers on the 29th, 30th and 31st of May, and the 1st and 2nd of June, at 5:30 p.m. Admission is free by ticket to be obtained from Mr. P. F. Rowell, secretary to the Institution.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, May 19th (to-day)

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Discourse on "Recent Experiments with Invisible Light," by Prof. R. W. Wood.

TUESDAY, May 23rd.

FARADAY SOCIETY.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment, W.C. Papers on "Recent Advances in Gas Thermometry," by Dr. A. L. Day; "The High Temperature Equipment at the National Physical Laboratory," by Dr. J. A. Harker, F.R.S.; "The Boiling Points of Metals," by Mr. H. C. Greenwood and "The Behaviour of Salicci at High Temperatures," by Mr. A. Blackie. Communications will be read "On the Maintenance of Constant High Temperatures," by Prof. Bodenstein and on "Stellar Pyrometry," by M. Féry.

THURSDAY, May 25th.

ELECTRO-HARMONIC SOCIETY.

6:30 p.m. Annual General Meeting at the Institution of Electrical Engineers, Victoria Embankment.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at Victoria Embankment. Paper on "The Heating of Cables with Current," by Messrs. S. W. Melsom and H. C. Booth.

FRIDAY, May 26th.

PHYSICAL SOCIETY.

3 p.m. Visit to the National Physical Laboratory, Bushy House, Teddington.

INSTITUTION OF ELECTRICAL ENGINEERS.

4:30 p.m. Annual General Meeting at Victoria Embankment.

SATURDAY, May 27th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

9 a.m. Visit to the Works of the Cambridge Scientific Instrument Co., Cambridge.

AUTOMATIC TELEPHONE EXCHANGE SYSTEMS.*

BY W. AITKEN.

Summary.—A description is first given of a switchboard designed by the author, in which the connection is made manually but disconnection is automatic. The full automatic telephone system of the Automatic Electric Co. is next described in detail. A comparison is finally made between the features of automatic and manual systems, and an estimate is made of the comparative cost of working.

In this country the development in the past has been almost entirely with manually operated switchboards. This type of switchboard has progressed from magneto-drop indicator and call-wire working, through various stages with mechanically and electrically restored indicators and branching jacks instead of series jacks, to the full common battery switchboard with parallel wiring and relays controlling lamp signals. From time to time automatic features have been introduced to simplify the operating, and thereby expedite the speed of connection. These automatic features have been principally introduced on the incoming junction switchboards which control the work between different exchanges in the same area, and where it is essential that the operating be of the very best. The insertion of the connecting plug into the jack of the line wanted, in addition to making the connection between the two lines, automatically cuts off the operator's testing circuit, introduces the supervisory signals, and in many cases connects up the ringing circuits so that the subscriber is automatically intermittently rung until he answers.

Keyless ringing incoming junction circuits have been designed both to expedite operating and facilitate maintenance. They allow of the number of incoming junction lines per operator being increased from 27 to 36, with actually less fatigue to the operator, and, by substituting a double make-and-break relay for the electromagnetic ringing key, the wiring of the circuits is greatly simplified and the cost per circuit reduced.

The British Insulated & Helsby Cables (*Ltd.*) have lately introduced small switchboards of my design, in which the connections are controlled by a rotary multi-contact electromagnetic switch, so that when a connection is made manually, it is held electrically and automatically disconnected, and all apparatus restored to the normal condition when the subscriber replaces the telephone receiver after a conversation. This will make the work from the private branch exchange to the central exchange much more positive, and prevent delays occurring at the central exchange due to slow operating at the private branch exchange. These boards are, primarily, designed for small exchanges where there is no regular attendant, say, up to 20 or 30 lines.

The multiple contact electromagnetic switch consists of a rotary selector arm which has an iron disc attached and is fitted over an electromagnet. The electromagnet sheath has the necessary groups of springs attached to connect with the number of extension lines required. Each group of springs is so arranged that when the rotary selector arm is depressed and the magnetic circuit closed, one set of springs breaks from inner ones, which disconnect the line indicator and battery of the extension line, and connect the extension line through to the exchange. The exchange speaking and holding key is linked up to the rotary switch in such a way that when the connection is completed by the rotary switch the holding key is automatically returned to the normal position. Fig. 1 shows the circuit for large boards.

Connector circuits are used, and these are the equivalent of cord circuits on ordinary boards. A relay is provided per line to cut off the local battery, when a connection is put through to the exchange, the electromagnet of the extension line then being in a local circuit; two plungers are depressed to complete a connection. As many connector circuits are provided as may be deemed necessary.

The operating is as follows: When a call is received from the exchange, the operator pulls over a speaking key and, at the same time, automatically restores the indicator shutter; after learning the requirements of the exchange the key is put to the holding position and the attendant rings the extension line wanted through the service switch, and after receiving a response moves the exchange multiple contact switch to 3 (if that is the number required) and depresses the key, when the current from the central exchange holds the electromagnet energised as long as the telephone is removed at the extension instrument. The winding of the electromagnet may be in series with the exchange line, and of 30 ohms resistance, and shunted by a condenser or non-inductive resistance of 70 ohms, so as not to interfere with the speaking efficiency. Instead of the switch electromagnet being placed directly in the line circuit, it may be replaced by a slow acting relay with the switch electromagnet connected in the local circuit. The advantage of this arrangement is that the switch-hook at the terminal station may be moved up and down to pulsate the lamp at the central exchange without disconnecting the circuit at the private branch exchange board. A second connection may thus be obtained through the central without the intervention of the private branch exchange operator. Where ringing current is supplied from the central exchange, the operating is improved by fitting a ringing key in connection with each extension line, so that the attendant, on receiving a demand from the exchange for an extension line, presses the ringing key and rings on the extension line until the line indicator shows a reply, and then moves the selector switch. This avoids the necessity of placing a holding coil across the exchange line whilst the operator is calling the extension.

The first full automatic switchboard used in this country was one patented by Mr. D. Sinclair, when engineer for the National Telephone Co., Glasgow, which was for single-wire circuits only, and was efficient for one junction line and five subscribers' lines. When a subscriber called, his indicator made contact with a sliding bar which connected the calling line to the junction line to the central exchange, and insulated all the other lines. A few of these were in use in Scotland for some time. Little more was done in connection with automatic telephony in this country—unless we take notice of exhibits made by Messrs. L. M. Ericsson of small automatic switchboards, which were in use in Sweden—until Mr. A. M. T. Thomson put forward his semi-automatic system, which was on exhibition for some time at the General Electric Co.'s premises about 1901.

In this system the number required was built up on the instrument and sent in to the exchange as a series of impulses which actuated an electromagnetic counter device which caused the number to be shown in front of the operator. The operator had no telephone, and mechanically, by the usual plugs and cords, connected the subscriber calling with the number revealed. The transfer system of working was adopted so as to save the multiple of the switchboard, and great claims were made for excessively speedy operating, but the system was never put into actual use.

In other countries, particularly in America, automatic systems have been put forward from time to time. In the early days there was the Strowger, Faller, and the Callander systems, and later, we find the Lorimer, the American Automatic Co., and others, but the only system that has *obtained* commercial success and has been introduced on a large scale is what was formerly known as the Strowger system, greatly improved by Keith, and others, and now known as the Automatic Electric Co.'s system.

Most of the leading telephone manufacturers are now busy developing automatic systems, but, practically, there is only one system in common everyday use—that of the Automatic Electric Co., of Chicago. It is claimed by this Company that there are 300,000 telephones working on their system, San Francisco, Oaklands, Los Angeles, Columbus, Grand Rapids, and Chicago, being among the largest installations. San Francisco and Los Angeles are both laid out on a basis of 100,000 lines. The former has already four exchanges with three at Oaklands, across the bay, most of them of 10,000-line capacity. Los Angeles has six main and four branch exchanges equipped for 25,700 lines. These exchanges are on the common battery system. The Chicago system is just being brought into use, and is said to be suitable for 1,000,000 lines.

The greater number of exchanges are on what is known as the three-wire system, the signalling being over the two wires alternately with earth return, but in San Francisco, and other later exchanges all signalling is effected by the intermittent opening of the circuit at the subscriber's instrument. This has greatly simplified the subscriber's instrument. All the facilities given on a manual exchange are now repeated on the automatic, and in some instances with a greater degree of flexibility. In a cosmopolitan city the advantage seems to be with the automatic as regards operating by the public.

The objection is commonly urged that the subscriber cannot be trusted to operate the switch correctly, and that he should not do more than lift and replace the receiver, all operating being done by a trained staff. This opinion, I think, is only held by a few enthusiasts now.

The author proceeds to describe the subscriber's instrument, the connector switch, the selector switch and line switch of the Strowger type as used by the Automatic Electric Co.* In the three-wire system the dial of the subscriber's instrument, as it revolv

* Abstract of a Paper read before the Institution of Electrical Engineers.

* These apparatus were described and illustrated in a Paper by Lee Campbell read before the American Institute of Electrical Engineers and of which an abstract was given in THE ELECTRICIAN of February 24 and March 4, 1910; and also in Sir John Gavey's "James Forrest" lecture (*see* THE ELECTRICIAN, July 1, 1910, p. 467).

Digitized by Google

intermittently earths one or other of the wires, and thus completing a circuit from a central battery causes step-by-step electromagnetic mechanism to perform certain functions. In the later system these functions are now performed by the dial simply intermittently opening the circuit which has been completed by lifting the receiver.

In the two-wire system the mechanism is very similar to that of the three-wire, but the electromagnets or relays controlling these are different. Advantage is taken of the slow-acting characteristic of relays having a mass of copper attached, so that two relays in series are actuated by the first completion of the circuit, but only one responds to the dial impulses.

The three relays of the line switch are now combined, in a most ingenious manner, into one having three armatures. The two-wire circuits of a 1,000-line exchange connection are shown in Fig. 2. The system of registering calls when the wanted subscriber answers is shown, and it will be noticed that the connection circuits are considerably complicated thereby.

When a receiver is removed to initiate a call—

1. A circuit is completed from earth 1, springs 2 and 3, line 4, receiver R, microphone M, line 5, springs 6 and 7, winding 8, springs 9 and 10 of master switch relay to battery. Armature 11 is pulled up and

2. Completes a circuit from earth 1, springs 2 and 12, through windings 13 and 14 to battery, and armatures 15 and 16 are attracted.

3. Armature 15 causes springs 3 and 6 to break contact from springs 2 and 7 and cuts the winding 8 from line. (The armature 11 is, however, momentarily retained by winding 14 until another

8. Relay 27 also puts earth on the wire 28 to the private bank to engage the line.

9. When the plunger 20 enters the group of springs 21, a circuit is also completed from earth by the contact *c* through the master switch bank contact 32, by bridge 33 to common connector 34, relay winding 35 to battery. All line plungers are, therefore, rotated to the next disengaged contact or junction by the relay 35 attracting its armature and allowing a spring (motor controlled) to revolve the shaft. Battery is also cut off all lines at springs 9 and 10, so that no call can be made whilst the shaft is rotating.

10. By the removal of the receiver only a subscriber's line has, therefore, been extended to a first selector by a junction line pre-selected; the line switch has been cut off the line circuit and is retained operated in a local circuit; one coil of the meter remains (for the present) in circuit in one wire; the calling line has had an engaging current connected to the private bank; the master switch has carried all the line switches of a group opposite the next junction to a first selector. The circuit is now ready for the dial impulses.

11. Suppose the number wanted to be 734. With the finger in hole 7 the dial is revolved to the stop and the circuit at the instrument is opened 7 times. The selector line relay 26 is de-energised momentarily 7 times. The release relay 27 is slow acting and does not de-energise.

12. Relay 26, therefore, completes a circuit 7 times from earth on middle spring, under contact, through lower back contact on relay 27, line 37, through winding of private magnet relay 37 (which is slow

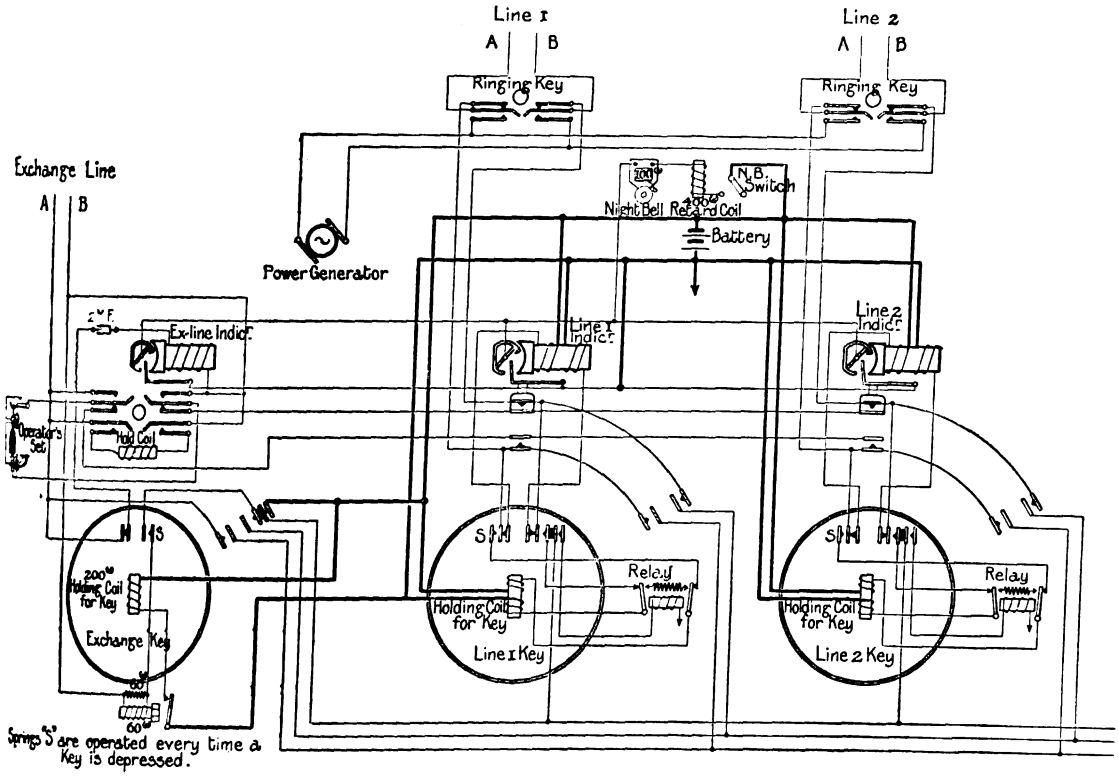

FIG. 1.—DIAGRAM OF COMMON BATTERY AUTOMATIC DISCONNECTING CORDLESS SWITCHBOARD FOR EXCHANGE SERVICE, WITH CONNECTOR CIRCUITS AND RELAYS.

...uit is completed, when armature 16 short-circuits winding 14 by ...tact 17 and 18.) Armature 16 carries the plunger 20, which ...cally engages with the moving vertical bar. When armature ... is attracted, therefore, the plunger 20 is forced forward until the ...rtical disc, passing between the springs in the bank, causes them ... make the contacts shown at 21.

4. Line 4 is then extended by contacts *d* of bank springs 21 and by ...ntact of side switch 25, through one winding of selector line relay ... to earth. Line 5 is extended through meter winding 27, contact ... of bank springs 21, through contact *a* of side switch 22, through ...other winding of line relay 26 to battery, and the line relay is energised.

5. This in turn closes the circuit through the guarding relay 27, which energising

6. Completes a circuit from earth 28, through upper contact of relay 27, contact *b* of bank springs 21, winding 29 of line switch magnet to battery, and this circuit maintains the line switch energised after winding 14 has been short-circuited.

7. Relay 27 also completes a circuit by line 28 through contact *b* of bank springs 21, through meter winding 30, contact 31, spring 17, and contact 18 of line switch to battery. As current is then through both windings in opposite directions the meter is not actuated.

acting and, therefore, remains energised after the first impulse), through winding of vertical magnet 38, through side switch 23 by contact *a* to battery. The vertical shaft therefore lifts the wipers to the seventh bank level.

13. Private magnet relay 37 when energised, by its springs, completes a circuit through the private magnet 41. The private magnet relay 37 de-energises after the seventh impulse, in turn de-energises the private magnet 41, and allows the side switches to pass to the second position, when

14. Another circuit is completed from earth 36, contact springs and winding of rotary magnet 39, through winding of guarding relay 40, through side switch 23 by contact *b* to battery. The wiper shaft is, therefore, rotated one step, and the wipers come to rest if that connector line is free. The rotary magnet 39 closes mechanically the armature of the private magnet 41 and also opens the circuit as shown at 39 by separating the springs. The armature of 39, therefore, falls back and the armature of the private magnet 41 also, and allows the side switches to pass to the third position.

15. If, however, the first connector circuit on that level is engaged, a circuit will be completed from earth through *b* wiper line 24, through side switch 24 by contact *b*, through private magnet 41 to

Digitized by Google

battery. The armature of private magnet 41 therefore remains attracted. The armature of the rotary magnet 39 is re-attracted and continues vibrating, at the same time moving the wiper *b* from contact to contact until a free line is obtained, when the private magnet 41 armature falls back and allows the side switch to pass to the third or c position.

16. The calling subscribers' lines (wires 4 and 5) are then connected to the selector wipers *a* and *c*; all selector electromagnets are cut off the line circuit, and the apparatus is maintained in the through position by the wiper *b* completing a circuit from earth through wire 24, side switch 24 by contact *c*, under contact of relay 40, line 27, through winding of release relay 27 to battery.

17. When the selector wipers *a* and *c* make contact with the line tabs on the bank the wires 5 and 4 are extended through the two windings of relay 42 to battery and earth, and this relay is immediately energised as the circuit is completed through the calling instrument. The wire 4 is extended by line switch bank 21, contact *d*, side switch 25 in *c* position, wiper *c*, line 4 and 4*a* bottom contact of relay 43, lower winding of relay 42 to side switch 47 by contact *a* to earth. The wire 5 by line switch bank 21, contact *a*, side switch 22 in *c* position to wiper *a*, by upper under contact of relay 43 to upper winding of relay 42 to battery.

18. Relay 42, when energised, completes a circuit from earth by back contact, through winding of relay 49 to battery.

19. Relay 49 completes the retaining circuit (relay 27) to earth from wiper *b* of selector, through upper back contact of relay 49 to side switch 45 by contact *a* to earth. Relay 49 is slow acting and does not de-energise when impulses are sent through relay 42.

20. No. 734 is being called, and so far the seven impulses have only been sent. The finger is now placed over figure 3 and the dial revolved, and the circuit at the instrument is opened three times, and the relay 42 pulsates three times.

21. A circuit is completed three times from earth by under contact of relay 42, back contact of lower group of springs, relay 49, line 50, through winding of P.M. relay 50, winding of vertical magnet 51, side switch 44 by contact *a* to battery. The vertical magnet, therefore, lifts the shaft with the wipers to the third bank level.

22. At the same time P.M. relay 50 has been energised and completed a circuit from earth by back contact of relay 50, through winding of P.M. 54 to battery, and P.M. has been actuated and has opened the line circuit.

23. Relay 42 remains energised and the circuit of the private magnet relay 50 is, therefore, broken; the private magnet 54 circuit is likewise broken, and it returns to normal, allowing the side switches to pass to the second position.

24. The finger is then placed in the hole over the figure 4 (the last figure of the number 734) and the dial revolved. Relay 42 is again actuated four times, completing a circuit four times from earth, by back contact of relay 42, back contact of lower group of springs 49, winding 50 of private magnet, outside under contact of relay 52, rotary magnet 53, side switch 44 by contact *b* to battery. The rotary magnet 53, therefore, moves the wipers to the fourth group of springs of the connector. P.M. relay 50 again de-energises, and if the line wanted is idle, the private magnet 54 is also de-energised and allows the side switch to pass to the third position.

25. The wire 4 of the calling line is then joined through condenser 65, under contact of relay 55, side switch 48 by contact *c*, to wiper *f* and one side of the called line; and wire 5 of the calling line by condenser 66, the contact of P.M. 54, and the upper under contact of relay 55 to the wiper *d* to the other wire of the called line, and a guarding potential or engaged test is placed on the line called at wiper *e*, from earth at side switch 46 by contact *c*, wiper *e*, winding 56 of line switch of called line to battery.

26. The line switch is energised, the armature 57 being attracted, and the circuit completed from wiper *d* by line 62 to the telephone, and the line switch coils cut off from the line called.

27. The side switch 44 in the third position completes a circuit

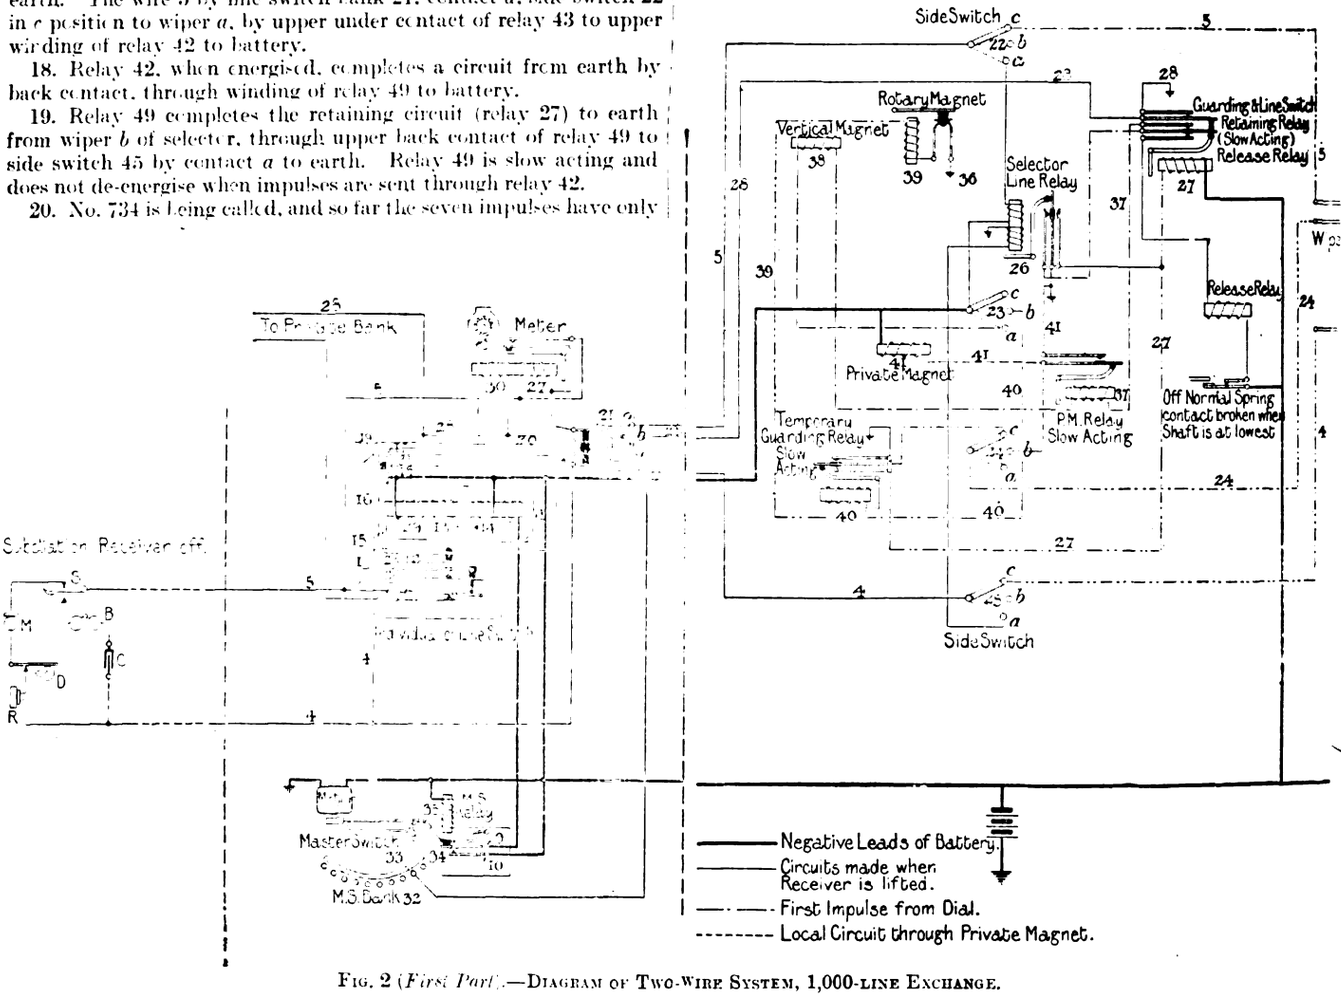

FIG. 2 (*First Part*).—DIAGRAM OF TWO-WIRE SYSTEM, 1,000-LINE EXCHANGE.

28. Relay 55 cuts off the calling line and intermittently connects the called line to the ringing generator 59.

29. When the receiver is lifted to answer, a circuit is completed from earth through side switch 46, by contact *c*, lower winding of relay 60, lower under contact of relay 55, side switch 48 by contact *c*, to wiper *f*, line 61, receiver R^1 and microphone M^1, switch hook upper contact, line 62, outer contact of line switch, wiper *d*, outer under contact of relay 55, contact of relay 54, to upper winding of relay 60, side switch 44 by contact *c* to battery. Relay 60 is, therefore, connected in bridge across the called line and is energised, and current is fed through the windings for the microphone M^1.

30. Relay 60 completes a circuit from earth through side switch 46 by contact *c*, relay winding 43, line 43, left-hand contact of relay 60 to battery. Relay 43 is energised, and a retaining circuit is then completed from winding 43, through middle upper contact of relay 43 through side switch 44 by contact *c* to battery.

Digitized by Google

31. Another circuit is completed by relay 60, from earth by side switch 46 by contact *c*, line 60, line 63, through right-hand back contact of relay 60, to side switch 47 by contact *c*, to lower winding of relay 42, so that the resistance of relay winding 63 is cut out of circuit.

32. Relay 43 when actuated as described in 29 reverses the connections between the called line and relay 42, the circuit now being from earth at side switch 46 by contact *c*, back contact of relay 60, side switch 47 by contact *c*, lower winding of relay 42, outer upper contact of relay 43, to the *a* wiper of the selector, line 5, through calling instrument, back by line 4 and *c* wiper of selector, lower upper contact of relay 43, to upper winding of relay 42, to battery.

33. It will be remembered that current is through both windings 30 and 27 of the meter, but in such directions that they neutralise. The reversal of the current by relay 43 now causes this to actuate and register. The meter contact closing short-circuits the winding 27 and the meter is retained in the energised position by the local wind-

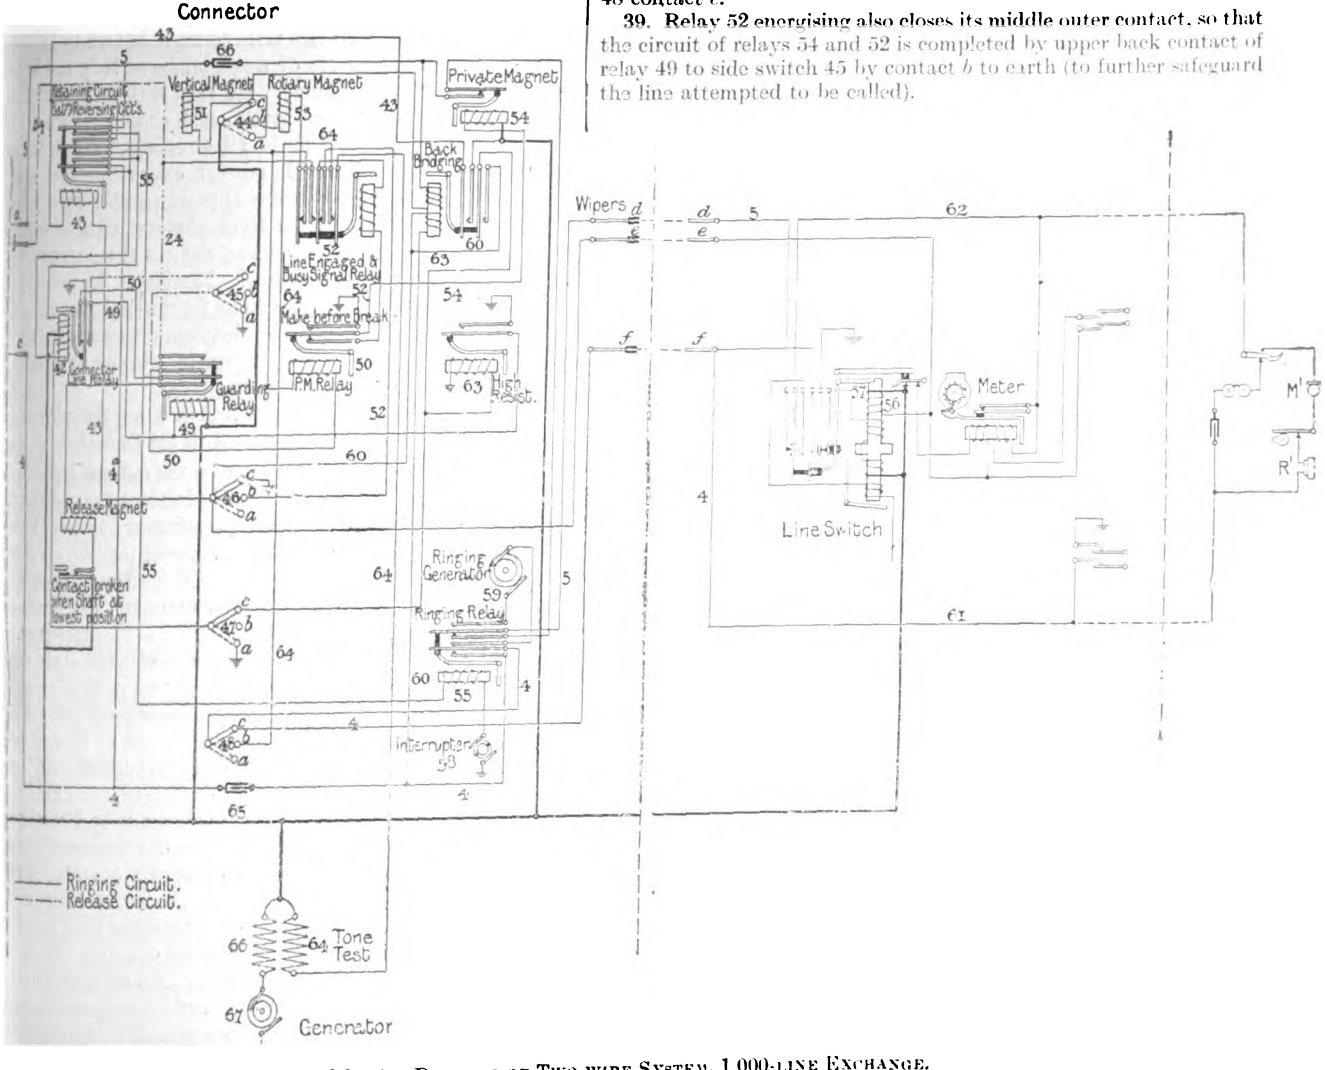

FIG. 2 (*Second Part*).—DIAGRAM OF TWO-WIRE SYSTEM, 1,000-LINE EXCHANGE.

ing 30. No action of either of the subscribers, therefore, can cause it to operate more than once.

34. Relay 63 is used in semi-automatic systems. Being first connected in series with the lower winding of relay 42 and then shunted by relay 60, additional current is sent to line, which may be utilised to operate a supervisory signal on a cord circuit. Being of considerable resistance, and to prevent trouble should relay 42 fail to act, the earth on back contact keeps relay 49 actuated.

35. When conversation is finished and the circuit opened by replacing the calling subscriber's receiver, relay 42 is de-energised. This opens the circuit of relay 49 of the connector and relay 27 of the selector, and both complete a circuit through the associated release magnet. The former from earth and under contact of relay 42, under contact of relay 49, through release magnet winding and contact to battery. The latter from earth and under contact of relay 26 to under contact of relay 27, through release magnet winding and contact to battery. The release magnets attract the dogs and thereby release the wiper shafts which are revolved by the controlling springs, until they fall by gravity to the normal position. In this position the release magnet contacts are open and cut off the battery. All circuits are broken and apparatus returned to normal position for calling.

36. Should the line called for be engaged there will be a guarding potential on the private bank of the connector. This circuit in the connection just described is from earth as side switch 46 at contact *c*, to wiper *e*, through winding 56 of individual switch, to battery.

37. Another connector wiper now making connection with the same line by a multipled bank contact will complete a circuit from earth by side switch 46 (contact *c*), wiper and bank contact *e* of the engaged line, contact bank and wiper e^1, side switch 46^1 by contact *b*, middle under contact and winding of relay 52^1, under contact of P.M. relay 50^1 (lines 52 and 54), private magnet winding 54^1 to battery, all on connector of the line attempting to call the circuit already engaged.

38. With the result that the private magnet 54 opens the circuit of the calling line, the other wire from wiper *f* is open at the side switch 48 contact *c*.

39. Relay 52 energising also closes its middle outer contact, so that the circuit of relays 54 and 52 is completed by upper back contact of relay 49 to side switch 45 by contact *b* to earth (to further safeguard the line attempted to be called).

40. The contact nearest the winding of relay 52 is also closed, and a circuit is completed from the secondary circuit of the busy signal machine 64, line 64, make contact of relay 52, side switch 48, by contact *b*, bottom under contact of relay 55, through condenser 65 over wire 4 and through calling instrument, and back by wire 5 to outer under contact of relay 43, upper winding of relay 42, and by common battery lead to the busy signal secondary winding.

41. The busy machine primary circuit 66 is from earth through interrupter 67, winding 66, through battery to earth.

42. When the receiver is replaced after the busy signal is heard all apparatus is returned to the normal condition.

43. If the line with which connection is desired originated the call, the engaging circuit will be from the selector earth 28, upper outer contact of relay 27, contact *a* of line switch bank, winding 29 of line switch to battery, with a branch to the private bank contact.

When an exchange is over 1,000 and up to 10,000 lines, a second selector is added. When a capacity of 100,000 lines is required, a third selector is used, and so on.

(*To be continued.*)

THE NOMENCLATURE OF PRIMARY AND SECONDARY SOURCES OF LIGHT.

BY A. P. TROTTER.

It is highly important that the terms used in optical science should be carefully defined, and it is equally essential that those employed in illuminating engineering should be clearly agreed upon. As in mechanical and electrical work, the scientific and the engineering vocabulary may differ slightly, and the mode of measuring the quantities may not be the same. But there must be *no* doubt of the meaning of any term.

The vocabulary at our disposal is so large that there is no need for coining new terms; on the contrary, some words may, perhaps, be excluded from scientific literature. Mr. Haydn Harrison has done well to call attention in his Paper read before the Illuminating Engineering Society* to illuminating units and their definitions, and those who do not altogether agree with him will appreciate the opportunity which is afforded for discussing the subject.

"The emanations from a light source" is too wide a definition of *light*. "Radiant light," wrote Lord Kelvin,† "is light if we see it: it is not light if we do not see it." *Light* is, I think, sufficiently defined as "visible radiation." I cannot agree with Mr. Harrison in coupling *luminosity* and *luminous intensity*. *Luminous intensity* should be the second quantity to be defined. As a matter of fact, the expression, though generally used in France, is seldom found in English, because we prefer the term *candle-power*. There are several ways of defining this quantity, but as there is no dispute about its meaning I will not stop to consider them.

The third quantity to be defined is *illumination*. "Remuneration," defined according to Mr. Harrison, would be "the extent to which anybody is remunerated." This is undeniable, but does not carry an engineer much further. In making definitions it is sometimes well to define the abstract idea independently of the measurable quantity. *Illumination* might perhaps be defined simply as the reception of light on a surface. This prepares us for similar definitions of the correlative idea of *brilliance*. The idea having been defined, a good quantitative definition of the British unit of illumination is "the illumination produced by one candle-power at a distance of 1 ft. on a surface facing the source of light."

Such a definition does not appeal to the mathematical mind. Dr. Rosa says‡ that illumination is the flux-density or flux per unit area on the surface where the luminous flux is received, and gives us the unit, lumens/cm^2. Blondel in 1894,§ in his valuable article on "Photometric Magnitudes and Units," gives a quantitative definition. "The illumination (*éclairement*) e at a point of a surface is equal to the ratio of the luminous flux which falls on a small element of surface to the area of this surface, $e = d\Phi/ds$." or "the illumination produced on a surface of 1 sq. metre by a uniform flux of the lumen." These are not quite the kind of definitions one would offer to a borough engineer for street work. They are rather like measuring rainfall as the ratio of the grammes of water to the area in square centimetres. The lumen is a valuable unit, but I do not think that English engineers are quite ready for it.

The idea connoted by the four terms *brilliancy*, *brilliance*, *intrinsic brilliance* and *brightness* is broadly the same, and is the emission of light from a surface. I am inclined to drop the simple term brilliance or brilliancy as a scientific unit, just as Blondel dropped *clarté*, and to use *brilliance* only in connection with *intrinsic brilliance*, which is the emission of light per unit surface. Quantitatively it is the candle-power per square inch or square centimetre. The mathematician who always spies 4π lurking in the background will prefer *lumens* or *millilumens* per square centimetre. Neither Blondel, Rosa nor Carl Hering draw any distinction between brilliancy of emission and brilliancy or brightness due to reflection. L. Weber, on the other hand, has suggested the distinction, and Mr. Harrison follows him. Abney proposed the term *luminosity* for "brightness resulting from illumination," but he uses it in discussing the brightness of different parts of the spectrum, and does not confine it strictly to reflected light. Rosa, in the Paper referred to, does not mention *brilliance* or *intrinsic brilliance*, but deals with *specific radiation* or *flux-density of radiation*. He uses "*brightness*" and "*surface brightness*," both in connection with a source of light and with the diffuse reflection from an illuminated body, and says that "brightness can refer equally to luminous sources of relatively high specific intensity or to reflecting and radiating sources of low intensities." But a "reflecting source" does not seem to be a good expression. He objects to the use by Blondel and others of e for illumination and radiation, as that gives rise to confusion.

The word "*surface-brightness*," which has been recently introduced in this country, appears to be a literal translation of "*flachenhelle*," and this term seems to be used by Liebenthal both for the brightness of a self-luminous body and for that of an illuminated surface. He says that each element of a glowing body, or, more shortly, each glowing surface-element, has the same *flachenhelle* in all directions,* and in the next paragraph he describes Lambert's observation that a white wall illuminated by the sun appears sensibly equally bright in whatever direction and from whatever distance one looks at it, . . . the *flachenhelle* of an element of the surface is constant at all angles of emission." Lambert in this passage† used *claritas*, a term which he used also for the brightness of a source. He insisted on the distinction between *illuminatio* and *claritas*, but in one or two places refers to *splendor*, apparently for the brightness of a self-luminous body.

Liebenthal seems to use *helligkeit* for the physiological effect on the retina proportional to the *flächenhelle*.

Blondel uses *éclat intrinsique* for the *intrinsic brilliance* of a self-luminous body as well as for the brightness of an illuminated object, and on page 265 of the "Illuminating Engineer" for April protests against any distinction between the two.

The term *luminosity*, having been defined by a high authority, has taken its place in scientific literature, but illuminating engineering is not quite the same thing as physical science. In electrical science we speak of difference of potential and electromotive force, in electrical engineering we speak of pressure or volts. The British public will probably prefer and will more readily understand *brightness* as measured by the new instruments invented by Dow and Mackinney, Edgcumbe and Trezise.

A difficulty in making the distinction recommended by L. Weber and by Harrison and objected to by Blondel is that the intrinsic brilliance or brightness of a translucent shade of opal or ground glass or of silk or paper, is due partly to transmission and partly to reflection. The fact that there are two different ways of measuring or of regarding these magnitudes does not make them separate physical quantities. Electricians are familiar with such magnitudes. A foot-pound is a unit of energy; it is also a unit of work; and it is sometimes convenient to regard it as 0·0018 horse-power-second. An ampere may be measured by volts per ohm., watts per volt, or coulombs per second, as is convenient; and we measure watts as volt-amperes, as C^2R, or as joules per second.

The obvious way of measuring intrinsic brilliance is to take the candle-power emitted per unit area. Luminosity, that is, brightness resulting from reflection, may be measured in the same manner, and from one point of view it is, therefore, the same physical quantity as intrinsic brilliance. The alternative to measuring luminosity by candle-power reflected per unit area is to assume a relation between the reflecting power of the substance and that of an ideal perfectly white and perfectly matt or unpolished material. An area of π square feet of such a material receiving an illumination of one foot-candle, or an area of one square foot receiving a uniform illumination of π foot candles, reflects one candle-power normally, and has a hemispherical candle-power of one-half candle. The experimental difficulty is the illumination of a surface of moderate size to give a measurable candle-power at a distance great

enough to comply with the law of inverse squares, say 6 or 8 times the greatest dimensions of the surface. Dr. Sumpner has done this* and has found to what extent various substances and coloured papers fall short of perfect whiteness, or unit albedo, as Lambert and modern astronomers call it. He found that white blotting paper reflected 82 per cent. It might be possible to equal this with white cardboard, but there is likelihood of error due to glaze. Compressed magnesia or barium sulphate has a high albedo and good diffusion, but Dr. Sumpner's careful test of the easily obtained material white blotting paper gives a valuable standard. The British unit of luminosity would be the luminosity of white blotting paper illuminated by 1/0·82, or 1·22 foot-candle. A circle of 1 ft. radius of the projected area of a globe of 1 ft. radius has an area of π sq. ft. A milk-white globe of translucent material of 1 ft. radius, having a light within it, and emitting 1 candle power in all directions, would be indistinguishable from a reflecting disc of white blotting paper of 1 ft. radius illuminated by 1·22 foot-candle. The intrinsic brilliance of the former would be identical with the luminosity of the latter. It is on this ground that I see no necessity for making a distinction. The luminosity of each would be that of a disc of unit albedo illuminated by 1 foot-candle.

I observe that Blondel considers that intrinsic brilliancy should be measured in the direction of maximum intensity. I am not aware that the intrinsic brilliancy of self-luminous vapours differs at different angles, though this is the case with all diffusively reflecting material that I have examined. I think it a pity to adopt white blotting paper or any other material as a standard. It is better to determine the absolute albedo, and this may be found with sufficient accuracy for ordinary purposes by assuming Dr. Sumpner's value 0·82, and comparing other materials with it.

Mr. Harrison has used the Whitman sector in exactly the same way and for the same purpose that Whitman did in 1892, namely for an investigation into the luminosity of papers coloured with various pigments. This led, two years later,‡ to the invention of the flicker photometer.

A NEW TYPE OF ELECTRIC FURNACE.§

BY CARL HERING.

The author devised some years ago the following method to make use of the force experienced in the "pinch phenomenon." Let Fig. 1 represent the cross-section of a cylindrical conductor; the "pinch" forces will then tend to act radially as shown by the arrows. If now the conductor be made to be a vertical column of liquid as, for instance, the part marked "resistor" in Fig. 2, consisting of a hole in a non-conducting material closed at the bottom by the electrode and filled with the liquid, then these forces will act horizontally and perpendicularly to the axis along the whole length. If the text-books are correct in saying "like currents attract," the mutual attractions of the parallel elemental currents in such a conductor would simply increase the current density in the centre. But, as the writer has repeatedly pointed out, this attracting force acts not on the currents alone, but on the material constituting the conductor, hence a suction would be created near the periphery and a pressure at the centre. However, these radial forces should in turn cause corresponding vertical forces at the centre and at the periphery, thereby producing a veritable fountain, as shown in Fig. 2, the liquid flowing up at the centre and down at the periphery, as indicated by the arrows; further, the direction of this hydraulic flow is independent of the direction of the electric current, and hence it is the same for direct or alternating currents. This fountain action was predicted by theory; experiment test showed that the prediction, and hence the theory, was correct; the forces and the consequent squirting turned out to be considerably stronger than was hoped for. It, in fact, constitutes a true valveless electromagnetic pump.‖

It will readily be seen that this new phenomenon, which was colloquially named the "squirt phenomenon," is admirably adapted to be made the basis of a liquid resistor furnace. If such a column is made the resistor in which the heat is generated by passing the current through it by means of an electrode at the bottom, the heated liquid will be rapidly expelled and forced to the top against the blanket of slag, while the cooler liquid at the bottom will be sucked down into the hole near the circumference to be in turn heated and immediately expelled with considerable force. With energetic circulation through the resistors, the fatal objections to the use of liquid resistors could be overcome.

In practice one would naturally use two holes, one for each electrode, as that reduces the depth of the hole to one-half. The proportions of the hole—that is, the ratio of the section to the length—are, of course, determined by the resistivity of the material, the amount of heat to be generated, and the relation of the volts to the amperes; the actual dimensions are therefore still a matter of choice. The ejecting force, or "squirting force," increases with the square of the current and diminishes as the cross-section increases. It will be seen therefore that there is some choice left as to the dimensions of these "flowing resistors," as they might appropriately be called.

In most materials there is apparently a very rapid rise of resistivity with the temperature, which is very favourable to the proportions of such resistors, as is also the apparently very rapid increase of the specific heat of iron at the higher temperatures. An analytical investigation of the relations of the various factors which determine the dimensions reveals some interesting and unexpected results. (These will be described in a subsequent Paper.)

The advantages of a furnace based on this principle are numerous. It is ideally simple and cheap, consisting merely of a crucible or hearth with two suitable holes in the bottom plugged with the electrodes. The heat is generated in the material itself, which is just

FIG. 1.

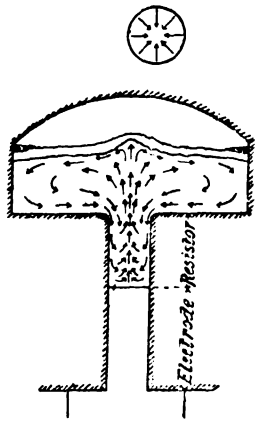

FIG. 2.

where it is wanted: moreover it is generated in the most rational place, namely, at the bottom and not on the top surface; it is conveyed and distributed mechanically, so to speak, throughout the melted mass, and this conveyance of heat is immensely more rapid than it would be by mere conduction or by the slow flow due to differences of density; hence a charge is treated and finished rapidly, whereby the output of the furnace per day is increased and the losses of heat per ton are proportionately reduced. As far as is known now, there is no temperature limit except that of the failure of the refractory lining, as the pinch effect can no longer limit the temperature.

This very active agitation and circulation of the liquid mixes the product rapidly with any of the refining ingredients which may be added, and tends to make the product very homogeneous. Every particle of the liquid is in turn, and repeatedly, brought to the surface where mechanically suspended impurities and gas bubbles are expelled and forced into the slag, and where the metal is exposed to the chemical action of the slag, which is so desirable and important in the refining of steel. Other advantages lie in the fact that the electrodes are very cheap, are not consumed, and as they may be made of metal they are far more economical in energy loss than carbon or graphite would be. No moving and adjusting of the electrodes are required. The interior of the furnace may be made as small as the quantity of the material to be held requires, hence the thermal efficiency of the walls of such a furnace could, no doubt, if desired be made to reach the practical maximum of all types of furnaces. Moreover, as the heat is rapidly distributed mechanically throughout the mass, the maximum temperature need be no higher than that required for the desired metallurgical or chemical action, hence the heat losses,

§ Abstract of a Paper read before the American Electrochemical Society.

‖ Dr. E. F. Northrup was the first to suggest and produce a vertical furnace by means of this pinch pressure, but the arrangement was quite different and could not be applied to furnaces.

Digitized by Google

which increase so rapidly with the temperature, are correspondingly reduced; in this there is a great advantage over arc furnaces, in which the temperature is necessarily that of the vapour of carbon.

The regulation is simple, rapid and, in fact, ideal; the resistance does not change appreciably with varying amounts of metal in the hearth; the resistance of the resistor, as determined by the voltage and amperage, may perhaps in some cases be an indication of the progress of the metallurgical treatment; and owing to the very rapid circulation, one can feel sure that the treatment is uniform throughout the whole mass.

There is an interesting feature in the fact that when the electrode is made of the same diameter and material as the resistor, the furnace should tend to become self-regulating as to temperature. When, for instance, the temperature becomes higher, the electrode automatically becomes longer and the resistor therefore shorter, whereby less heat will be generated; and the reverse when the temperature becomes lower. The place where the electrode ends and the resistor begins is, of course, that section across which no heat flows; the heat generated below this section flows out to the terminal, and that generated above it flows into the furnace; it is this plane that automatically moves up or down.

The counter E.M.F. which must necessarily be generated by the movement produced is an advantage, as it shortens the resistor, and the energy corresponding to this counter E.M.F., of course, also ultimately generates heat by friction, and is therefore recovered.

By using a bath of some suitable metal in the bottom of the furnace as the prime receiver of the heat, the furnace is adapted to be used to melt non-conductors like glass, or to heat granular ores, reduce and volatilise such metals as zinc and arsenic from their ores, &c. By dissolving carbon in the iron in one part of a bath, and the oxide in another part, iron can be reduced from its ores, and the CO gas produced can be burned to preheat the ore, whereby the total energy of the carbon may be utilised, notwithstanding the fact that an authority recently said this was theoretically impossible. The power factor can, of course, be made very high, probably practically unity, and unlike in the induction furnace the frequency need not be abnormally low.

An interesting feature of the principle on which this type of furnace is based is that, contrary to the more usual cases, the larger the furnace the better, and the less will be the difficulties, because the resistors then become shorter and thicker. There are, of course, many modifications which at once suggest themselves, and which will be tried in due course. It would be quite simple, for instance, to add gaseous fuel heat, or the heat of an arc, in the upper part; or to add the electrical parts to existing open hearth or other furnaces and use the electric heat only for the final treatment.

The transformer is best attached directly to the bottom or side of the furnace, as the furnace currents are, of course, of low voltage, hence large in amperes. The flexible connections to a tilting furnace then, consist merely of the two thin primary wires. The furnace is readily adapted to three-phase current.

THE ELECTRICAL EQUIPMENT OF A MODERN THEATRE.

BY D. C. M. HUME.

The art of amusement and the science of relaxation have now been brought to such a pitch of advancement that the various apparatus employed therein have long ago passed the makeshift stage, and it is now the exception to find any but the best of machinery in even the minor haunts of happiness.

To the engineer there is much of interest in the installation of a modern theatre, and very weighty problems in mechanical and electrical equipments are often to be solved. Considerable weights have to be handled expeditiously; considerable areas have to be economically lighted; certain effects must necessarily be to hand; heating and ventilating have to be studied, and in all this the consulting engineer has to be a very all-round engineer to control the business, especially when under the stringent rules of the L.C.C. and certain other governing bodies to whom the safety of the public is a sacred thing. These regulations may always be obtained by anyone interested, but are of too bulky a nature to include in this article. They chiefly treat of such points as compulsory alternations and separate lighting supplies, visible and perpetual exit signs of specified dimensions, fireproof curtains, insulation tests, conductor sizes, &c., all of which necessitate a certain standard of excellence in every installation. This is not only conducive to public safety, but tends to eliminate the cheap job and to dignify the contractor's calling.

Leaving for the time being the architectural and ironwork engineering, which, in the average theatre, is a splendid example of cantilever construction (for example, the Coliseum and Palladium in London; Olympia, in Liverpool, &c., where the absence of pillars is so conspicuous), the stage and flies produce the chief problems from a mechanical point of view.

Stages may be revolving (Coliseum), lifting (Drury Lane), or

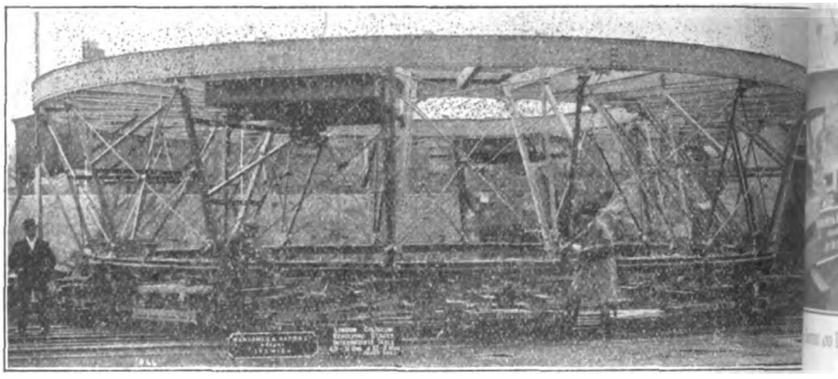

FIG. 1.—INTERMEDIATE RING OF LONDON COLISEUM REVOLVING STAGE.

even sliding. Apart from this, there may be conveniences for mechanical scenery, such as a traverse beam, panoramic gear, power winches, electric and hydraulic lifts, tilting stages, &c.

Revolving Stage.—The best example of a revolving stage is to be seen at the London Coliseum. This stage, which weighs 160 tons, was designed by Mr. E. Wingfield Bowles after many experiments, and is so constructed that it provides facilities for a great variety of spectacles and, at the same time, is the finest method of scene changing yet devised, providing, as it does, a

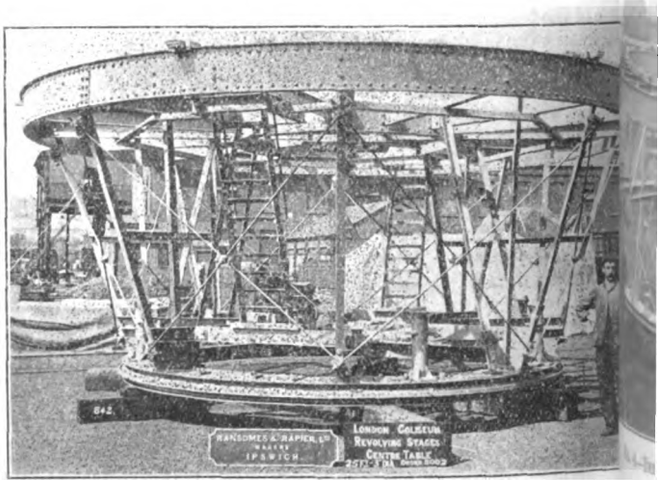

FIG. 2.—CENTRE TABLE OF LONDON COLISEUM REVOLVING STAGE, SH ACCESS LADDERS.

"full set" for every "turn"—that is, a deep set scene complete with side wings and cumbersome furniture, &c., &c.—whereas in a fixed stage short sets or "front cloth" scenes have to be interspersed throughout the performance often to the detriment of the "turn" allocated therein.

The Coliseum stage is 75 ft. in diameter, and around the circle abuts the stationary part of the stage. In all, the available area is 10,000 sq. ft. The main table or revolving stage is divided into three concentric parts, which can be locked t

Digitized by Google

gether by flat hinged tablets of iron let flush into the upper surface of the stage or allowed to run separately as independent units. The upper surface is of 3 in. teak radially laid. The outer ring carries mast holes and sockets whereby it was originally intended to support scenery, but the use of these has been discontinued, as they were found to be cumbersome and unsatisfactory. The intermediate ring carries further mast holes and two water tanks of 1,000 gallons capacity, which serve usefully in water spectacles, dives, &c. The centre table carries one trap which admits by way of a staircase to a special

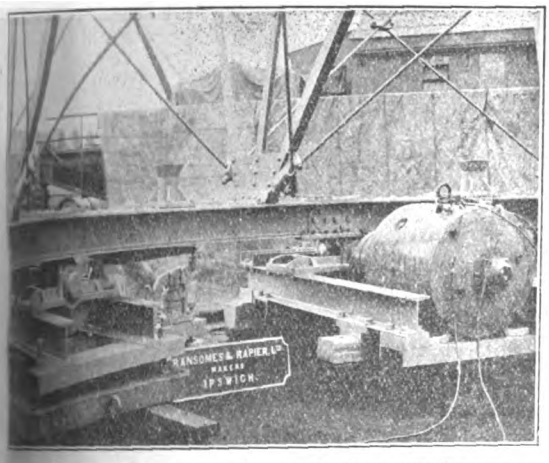

Fig. 3.—Method of Driving and Levelling Coliseum Stages.

stationary platform below, from which the chorus or other performers may be safely "fed on" to the stage even when it is running.

The underside of the stage is a very weird sight, especially when revolving at high speed. It gives one the sensation of being in a continual bridge collapse. Each ring is built upon inverted A frames, at the apex of which is fixed a circular H-rail; this runs on the pulleys of the driving motors, which are themselves stationary. Intermediate levelling wheels are provided, and also centring wheels bearing on a special rail

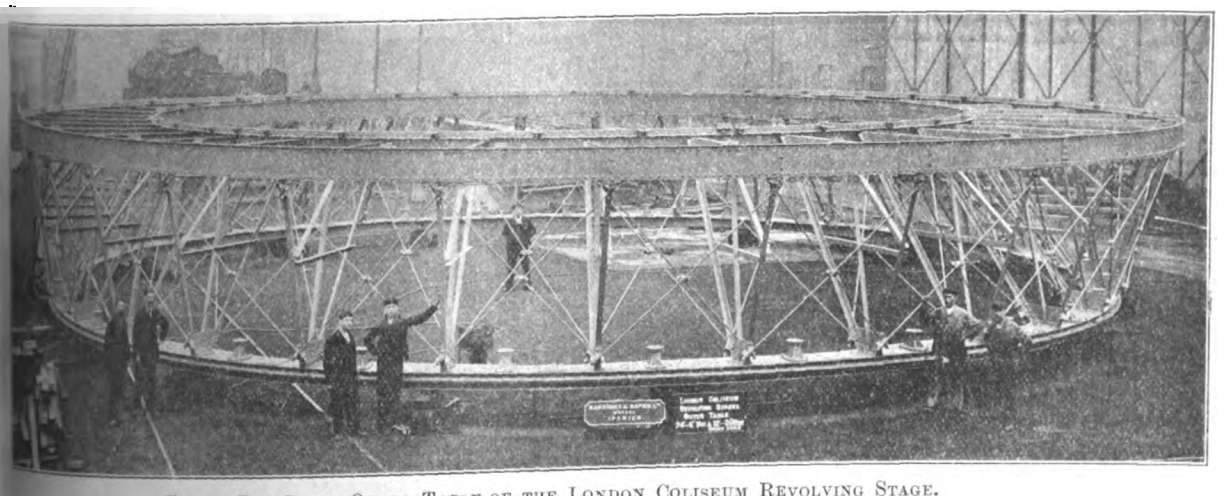

Fig. 4.—The Great Outer Table of the London Coliseum Revolving Stage.

mounted upon the side of the running rail. The diameter of the outer table is 74 ft. 6 in. on the iron crown rail, that of the intermediate being 49 ft. 11 in., and the centre table 25 ft. 3 in. Thus the radial dimensions are approximately 12 ft. 3 in. for each section. The whole depth from crown to running rails is about 11 ft. 6 in., and each ring is electrically and mechanically a separate unit. The maximum gap allowed in the floor grooves on the stage surface is 2 in. The motors are 14 in number, averaging about 15 H.P. each. Two of these drive the centre table, four the intermediate and eight the outside ring.

At top speed the outer edge of the table travels at about 25 miles an hour. Electric and hydraulic brakes are provided which can pull the tables up dead in 2½ revolutions from full speed. The stage was made by Messrs. Ransome & Rapier; various views of it are given in Figs. 1 to 5.

A special switch room is installed for these tables and contains auto-cut-out and fuse panels and the controllers' resistance banks. The controllers themselves are situated in a separate fireproof chamber immediately below the main switchboard platform, and are operated therefrom by means of a winch-handled worm-gearing turning an indexed brass plate mounted on the upper extremity of a vertical shaft, of which the lower extremity gears with the controller drum in the room below. The controllers stand 6 ft. high, and contain some 90 contacts, arranged to start up the machines in series, then parallel in pairs and finally parallel individually with the necessary intermediary resistance steps. The controllers and motors were supplied by the Sturtevant Engineering Co.

Panoramas.—Panorama gear provides a tricky problem, and many are the suspensions that have occasionally been tried, but difficulty is experienced in most designs, either owing to the clips or suspension jambing in the guides, or the cloth climbing the rollers. On the whole, the best system is that used at Earl's Court and at the London Coliseum. The cloth is sewn on to a length of 2¼ in. rope (¾ in. diameter), and from a suitable girder or beam are suspended in pairs vertical rollers about 9 in. deep and 6 in. in diameter. These are machined with a 1 in. shoulder on them, and are arranged to hang ¾ in. apart, and above them is threaded the cloth rope. The rollers are machined all over. The rope carrying the cloth cannot, therefore, drop between the rollers, and so runs on the upper face of the shoulder with the minimum of friction or obstruction. One great advantage of the above panorama suspension is that it will adapt itself satisfactorily to curved or discorced paths.

To minimise noise and economise power the panorama rollers are fitted with roller bearings. It is usual to drive the main panorama drums, which are about 2 ft. in diameter and extend the full height of the scenery (in the case of the Coliseum, 30 ft.) by a worm-gear from under the stage.

Lifting Stage.—Lifting stages are divided into a series of transverse platforms, about 10 ft. deep, which can be elevated into the air about 12 ft. or so, or sunk below the stage level for about 6 ft. These are usually hydraulically operated, and may be seen in use at Covent Garden or Drury Lane almost any night. Their underneath construction is very simple, as they are little single-span bridges running on vertical end guides, and operated by wire cable and a double-winding winch or hydraulic ram. Careful provision against the unequal stretching of the cable and consequent jambing of the guides must be made by compensating pulleys, &c. Hydraulically operated bridges seem to give the best results in practice.

Sliding Stages.—Sliding stages have only been installed in large opera houses on the Continent, and scarcely justify the wasted room they entail. In these the whole stage and scenery

Digitized by Google

slide sideways across the proscenium, opening like a vast lantern slide.

Special Scenic Gear.—A traverse rail is a useful adjunct to a stage where spectacle is to be provided, and a good example of this is to be found at the Coliseum, where a single rail runs from the scene dock to the opposite fly floor right across the centre of the flies, and carries on it a travelling crane motor of 4 H.P., which can be attached to hanging platforms reaching to within about a foot of the stage; it can tow them across the stage at about 20 miles per hour, if required, when loaded up to 11 tons. A safety cut-out brake gear is provided to obviate any possibility of accident through overrunning. Loaded with a human freight these platforms make a telling climax to a panorama.

For any particular job such as storage battens for stock cloths, &c., power winches of the usual self-contained type are used. Power curtains other than fireproof are rare, but have much in their favour, as they can be definitely counterbalanced and fixed, whilst electric control admits of perfect speed variation.

Fireproof Curtains.—Under the L.C.C. regulations, the fireproof curtain must be hydraulically operated, and provision must be made for a control next the stage door whereby the watchman can at any moment, in case of emergency, let down this cumbersome screen, and so absolutely shut off the stage from the auditorium. It is not unusual for a fireproof curtain to weigh several tons; they are about 6 in. to 8 in. thick, and

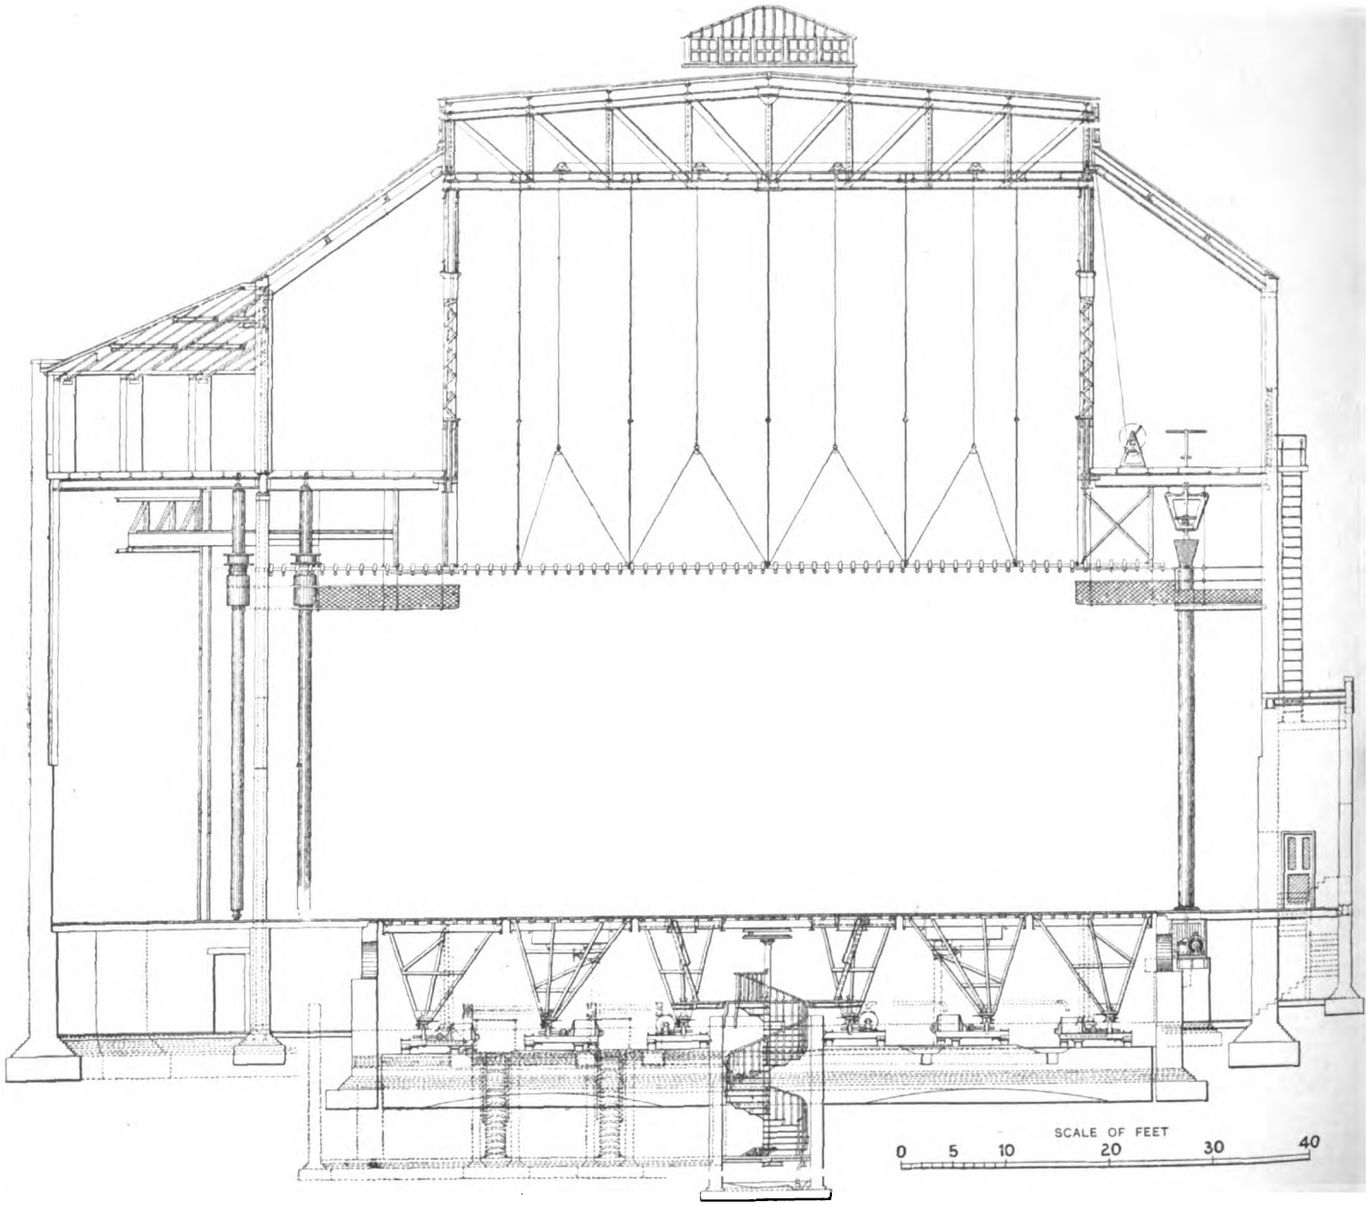

FIG. 5.—SECTION OF THE LONDON COLISEUM STAGE, SHOWING TABLE AND PANORAMA GEAR.

Mechanical Flies.—The mechanical operation of the "flies" is fairly simple, for the reason that it is seldom a success. There are so many "lines" to be dealt with (three to each cloth in most places), and these have to be easily adjusted, made off, slacked out, &c., that any discriminating winch device is, in effect, impracticable. There have been devices patented, and at times installed, consisting of multiple winches on a common power spindle, and arrangement for clutching on and letting go, &c., but they have generally proved themselves a greater nuisance than convenience. They have a tendency to be "fierce," or else to drop their load. Flymen usually prefer to counterbalance the cloths carefully and hoist by hand.

are made of asbestos sheeting and wool mounted on an iron frame very carefully under-counterbalanced, and kept in the up position by pressure from hydraulic mains, which arrangement recently led to the premature closure of several theatres owing to the bursting of the main in the centre of London's theatreland. A hand winch gear is usually provided to cope with such contingencies. The Drury Lane fire was a splendid example of the efficiency of these curtains. Here the whole stage was gutted and yet the auditorium remained untouched. This curtain was the work of the fire specialists, Messrs. Merryweather & Co., as indeed are most of the curtains. Whilst on the subject of fire it may soothe the unsophisticated reader's minds

Digitized by Google

to know that all dresses, scenery, properties, &c., are compelled by the L.C.C. regulations to be rendered fireproof by immersion in an approved liquid agent. Something more than stencilling the word "Fireproof" is required. Adjacent to the watchman's fire curtain control is another handle, operating the "sprinkler," a device for producing a miniature rain storm along the proscenium arch in case of fire.

Lifts.—The dressing rooms lift is a great convenience to the producer in any theatre, as it provides a quick way for the chorus to reach their rooms, and so facilitates quick changing. For pantomime, ballet and spectacle this is a positive boon, and should never be left out of a new design if avoidable.

Passenger lifts for the auditorium have not been highly favoured in this country, though in America they are often to be found. In London, they may be seen at the Coliseum and the Playhouse, and serve to feed the first circle and the tea room, though these are, we believe, the only theatres that have them and consistently use them.

So much for the power installations of a theatre. We may now turn to the subject of lighting.

(To be continued.)

THE BENKÖ PRIMARY BATTERY AND ITS APPLICATIONS.*

BY W. B. COOPER, M.A., B.SC.

Principle of the Benkö Cell.—The cell is due to the Hungarian engineer Stephan Benkö, and depends essentially on the idea that if the layer of electrolyte on the positive plate (that is, electro-negative

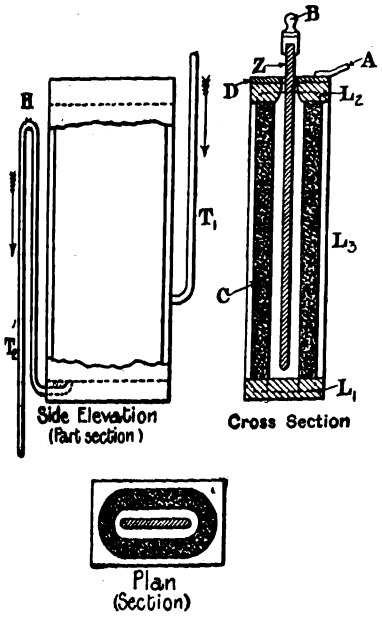

FIG. 1.—DIAGRAM OF BENKÖ CELL.

element) is removed as fast as polarisation sets in, the E.M.F. will be maintained constant. The remedy adopted by Mr. Benkö is to use a carbon electrode sufficiently porous to allow the electrolyte to flow through it, thus continually providing a fresh supply to the surface that is tending to polarise. By so doing not only is very effective depolarisation obtained (depending, of course, upon the depolarising qualities of the solution and its rate of flow), but for a given current the polarisation remains quite constant provided the cell is not overloaded.

The method of putting this idea into practice will be understood more readily by a description of the cell as at present made.

Description of the Cell.—For the sake of clearness the construction is indicated first diagramatically in Fig. 1. Here the carbon is shown at C, and this is best described as a flattened cylinder open at both ends. The hard surface of this carbon, as received from the carbon maker, is removed by scratch-brushing so as to leave it easily porous. The carbon is then provided with a lead cap, L_1, at the bottom, and a lead ring L, at the top, thus providing a vessel open only at the top. A lead shell, L_3, of sheet lead 1 mm. to 1½ mm. in thickness, is then fitted round the carbon, leaving a small space between the carbon and the shell, and is jointed autogenously to the lead cap at the bottom and the lead ring at the top, so as to form a chamber all round the carbon. We thus have two chambers, one inside the carbon and one outside. The outer chamber is provided with a tube, T_1; and a second tube, T_2, is fitted to the lead base and is carried through to the inner chamber. This latter tube is carried up and bent over, and there is a small hole, H, at the top of the bend. Finally, a copper plate, D, corresponding with the lead ring, is soldered on to the lead, and forms one terminal, A, of the cell.* The zinc, Z, is inserted into the inner chamber and carries the second terminal, B. When in action the electrolyte is delivered by the lead tube, T_1, into the outer chamber, whence it percolates through the carbon to the zinc; it then flows off through the lead tube, T_2, the form of which maintains the level constant within the carbon. As there is a hole at H, syphoning does not occur, though this may be made to take place in cells so constructed by closing the hole with a finger for a few minutes. This is often convenient when it is desired to empty the cell. It will be noticed that the current is carried away from the carbon at both top and bottom, and owing to this form of construction, and to the excellent contact between the carbon and the lead, very much heavier currents can be taken than is possible with the usual form of joint.

A working drawing of what I will term the "Type A" cell is reproduced in Fig. 2, in which the lettering of Fig. 1 is retained as far as possible. The zinc plate is carried in an ebonite frame F. The tubes T_1, T_2, are provided with unions and rubber washers, W_1, W_2, for coupling to other tubes as may be found necessary.

Fig. 3 is a view of a single cell with casing, being one of those which

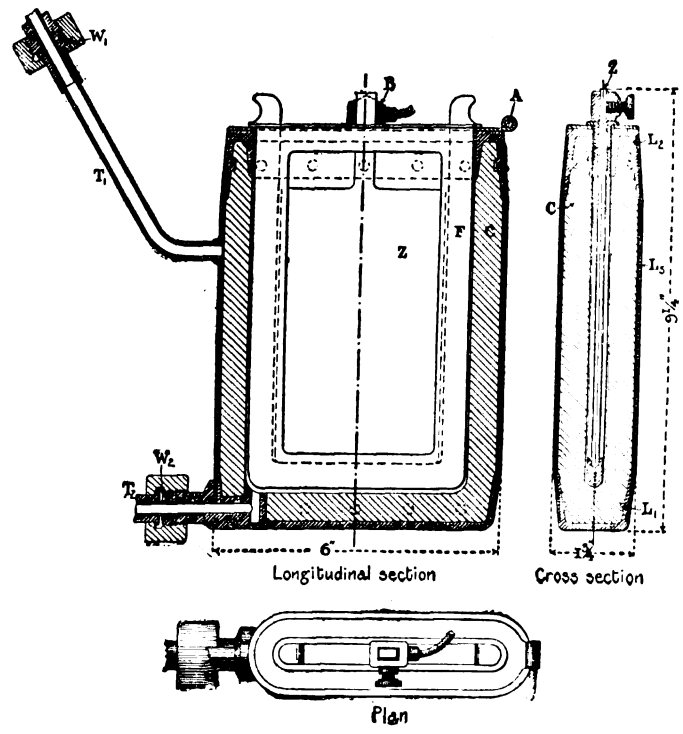

FIG. 2.—SINGLE BENKÖ CELL (STANDARD TYPE.

were tested. It differs in some small details from the cell shown in Fig. 2.

The carbons at present are not made larger than is shown in Fig. 2, but if larger cells are required this is effected by fitting two or more carbons into one shell. These are thus permanently connected in parallel, and the zincs are correspondingly coupled together.

The particulars of the "single" cell are :—

Width	1¾ in.
Length	6¼ in.
Height (including terminals)	9¼ in.
Weight (including zinc)	8·8 lb.
Maximum current continuously with L solution	17·5 amperes
Power	26·25 watts

The current stated is for a voltage of 1·5 volts per cell, the E.M.F. being 2 volts.

In the case of a battery the electrolyte is contained in a lead-lined tank, from which it flows (due to its own head) down to a common supply pipe from which each of the cells is supplied by a tube, the

* Abstract of a Paper accepted by the Institution of Electrical Engineers.

* In later designs this copper plate has been abandoned, the terminal being jointed direct to the lead ring.

Digitized by Google

junctions being by ebonite unions and rubber washers, as already described. Similarly the waste from each cell is carried into a common waste pipe, from which an inverted U pipe is taken to maintain the level in the cells, and this discharges into a lower tank. By means of a cock the common waste pipe can be opened to this tank so that the cells can be drained when the supply of electrolyte has been cut off. The arrangement is compact, the width across the front of the stand being only 25½ in. and the depth from front to back being 24½ in. In order to give the necessary head the overall height is 7 ft. 9 in. for a 7-cell battery (and has recently been reduced.) Air pressure might, of course, be used instead of a gravity feed; this would give greater compactness and might be preferable under certain conditions. But even with the arrangement shown, for a battery giving a minimum working pressure of 10·5 volts and a power up to about 260 watts continuously, the space required must be regarded as small.

Tests.

Constancy of E.M.F. and Current.—With a given flow of electrolyte an extremely constant current can be maintained up to a certain limit. This limit depends largely, of course, upon the composition of the

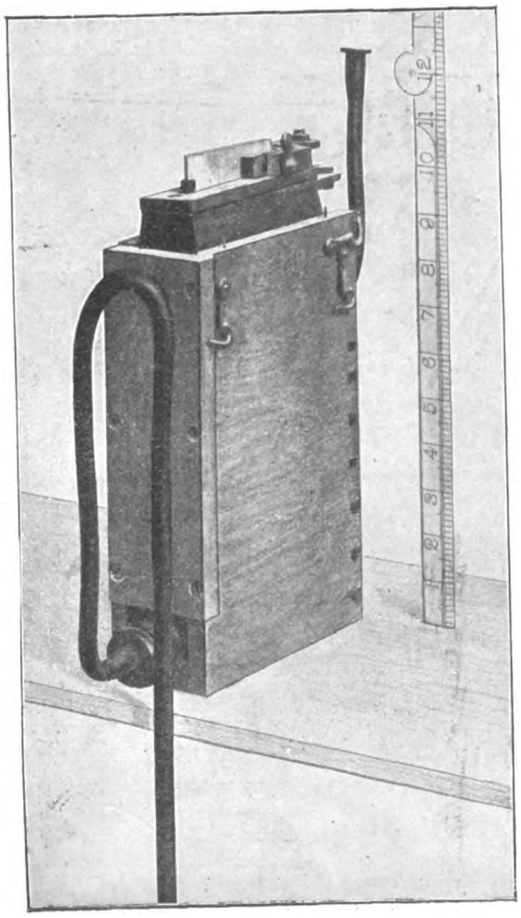

Fig. 3.—View of a Single Benkö Cell used in Tests.

electrolyte. Various electrolytes may be used, and in the case of bichromate solutions Mr. Benkö recommends the following formulæ: For electric light, 60 grammes of sodium bichromate and 120 c.c. of sulphuric acid per litre of water (solution "L"); and for heavy currents 100 grammes of sodium bichromate and 150 c.c. of sulphuric acid per litre of water (solution "P").

The limiting currents obtainable continuously with the two first solutions in terms of the area of the zinc (taking both sides into the measurement) may be taken as follows:—

	Per square decimetre.	Per square foot.
Solution "L"	6 amperes	..... 56 amperes
Solution "P"	10 „	..... 93 „

Local Action.—With an acid electrolyte there must always be a certain amount of local action, and this can be measured. In the present case, however, it is impossible to give any definite figures for this loss in a general way because it varies with the flow of electrolyte and with the current taken from the cell (owing to the fact that this alters the composition of the electrolyte) and with the state of the zinc. It might be thought that serious local action would take place through the tubes connected to the common supply of the electrolyte on the one hand and to the common waste on the other. There is, of course, a potential difference between the tubes of one cell and those of another, but this is localised by the ebonite unions and rubber washers used for coupling up the pipe work, and so far as could be seen no corrosion of the tubes took place during the six weeks this particular battery of four cells was under test. As to how many cells could be coupled up in this way without giving trouble through local currents it is difficult to say.

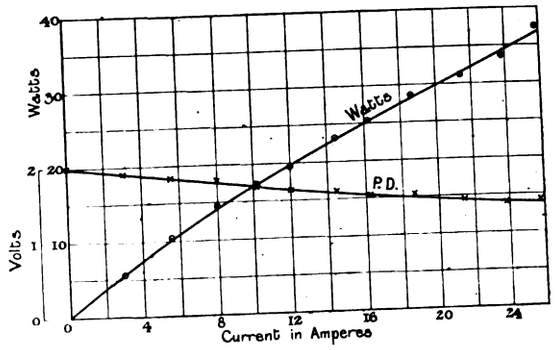

Fig. 4.—Relation of Terminal Volts and Terminal Watts with Amperes.
Type "A" cell. Solution "L."

Internal Resistance and Polarisation.—It is difficult to separate these two quantities with certainty, and no attempt has been made to do so. Fig. 4 shows how the terminal pressure and terminal watts vary as the current is increased. The currents were not taken momentarily from the cell, but the external resistance was decreased step by step as quickly as the readings could be taken, and therefore polarisation no doubt reduced the higher current readings to some extent. The highest outputs shown would not be maintained for any long periods, as the cell is overloaded. This test was made with solution L.

The test shown in Fig. 5 was made with a similar single cell, using the stronger solution P at a head (between the bottom of the tank and the top of the overflow tube) of 45¾ in., which gave a flow of about 1·9 litres per hour. In this test the external resistance was maintained constant, and the fall of current was observed for minutes. The current might have been maintained longer, but the cell became very hot with such a heavy discharge.

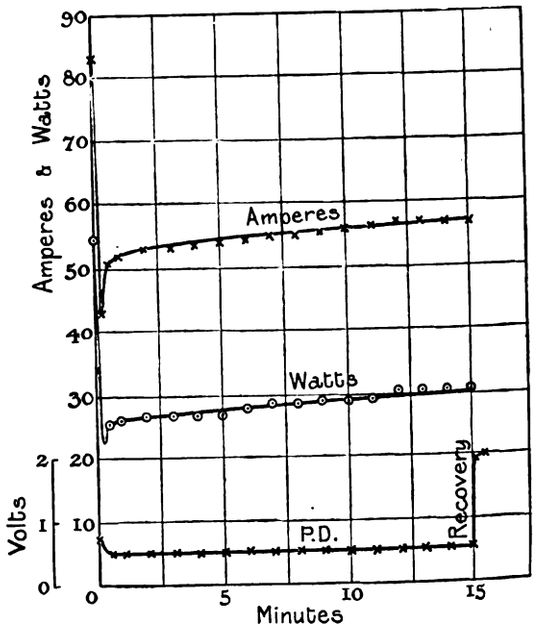

Fig. 5.—Heavy Current Test on Constant Resistance.
Initial Current 83 amperes. Type "A" cell. Solution "P."

Short-circuit tests with the L solution showed momentary currents of 100 amperes at a terminal voltage of 0·5 to 0·6 volt, the current falling to 80 amperes at the end of 5 seconds. With the stronger solution momentary currents of 200 amperes were taken at a terminal pressure of 0·5 to 0·55 volt. It follows, therefore, that the internal resistance is well below 0·01 ohm, an extremely low figure. T

Digitized by Google

result is no doubt due largely to the excellent contact between the lead shell and the carbon, both at the top and at the bottom.

Omitting the tank, for which it is difficult to make an allowance, the Benkö cell compares favourably with accumulators as regards current output per square foot of plate, power per pound and power per volume.

Applications.

Laboratory and Miscellaneous Uses.—The Benkö cell has the advantage that it is small, easy to handle, and requires no careful attention. When it is not required it can be left on one side without fear of deterioration, the only desirable precaution being the running of some water through it to free it from the used electrolyte after heavy work. The laboratory, the charging of ignition cells, electro-plating on a small scale, and possibly submarines (owing to the peculiar conditions involved) are fields in which such a battery would prove useful. There is also the electric lighting of yachts having no generating plant. At present this is sometimes effected by means of accumulators which are taken ashore for charging as opportunities may arise. Such a method, however, has obvious drawbacks and limitations, and a convenient primary battery would, no doubt, be welcomed as a substitute.

Telegraphy.—Although accumulators are being employed increasingly in telegraphy, owing to their small internal resistance there are many cases in which they cannot be so applied, and therefore large numbers of primary cells are still in use for telegraphic work. Amongst these, bichromate cells of the quart and three-pint sizes figure largely and involve a good deal of cost and work in their maintenance.

In order to show the capabilities of the Benkö and ordinary bichromate cells (without porous pot), the curves in Figs. 6 and 7 are given. Fig. 6 shows the record taken by a recording ammeter of the discharge of an A type Benkö cell along with plotted curves of terminal pressure and terminal watts. It is seen that a remarkably constant current of over 12 amperes was taken from the Benkö cell for six hours and the current was then increased to over 17 amperes for about two hours.

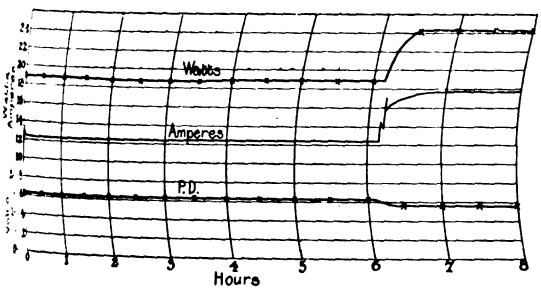

Fig. 6.—Discharge Curves of Benkö Cell.
Type "A." Solution "L."

The bichromate cell used for comparison held three pints of the same electrolyte and had one zinc plate and two carbons; all three plates were 6¼ in. wide and were immersed to a depth of 7¾ in. The area of the zinc was more than double that of the Benkö cell, and the carbon surface also much greater (though a little less in proportion). Yet when this cell was switched on to the same circuit as that which carried 12 amperes in the test just referred to, the current, which rose momentarily to 9·6 amperes, fell quickly below 8 amperes, and continued to fall as shown in Fig. 7.

Where the currents used in telegraphy run merely to some milliamperes, it will be seen that Benkö cells very much smaller than the type A (for example, less than a quarter that size) would give the necessary current for telegraphic work. Such cells have been made, and they present the advantage of occupying a much smaller space than the usual primary cells, and, moreover, are equivalent to the best accumulator in constancy of E.M.F. and low value of internal resistance. Obviously also they would be much simpler to keep in order than a battery of ordinary bichromate cells. A type of Benkö cell has also been developed in which the compartment outside the carbon is filled with very strong electrolyte and the inner compartment is merely filled with water; circulation of the electrolyte then takes place by diffusion, there being no supply and waste pipes, or pressure reservoir. Probably cells of this kind will be the most suitable for telegraphy and for miners' lamps where only small currents are required.

Country House Lighting.—Country houses above a certain size can be supplied very efficiently with electric light by the usual type of private plant. But if the house is below a certain size (for example, one requiring 50 10 c.p. lamps), an oil engine set, with its attendant accessories, presents very marked disadvantages. There is often difficulty in providing the necessary skilled labour, and the smaller the installation the more important the capital charges become. In such cases an owner would often be willing to pay a high price per unit if the first costs were low and the battery could be worked conveniently. Taking market prices for materials the cost per unit is found to be about 2s. per unit, but varies with the conditions. This cost is not prohibitive, and even 2s. 6d. per unit would not be out of the question. The smaller the house the more favourable is the position of the battery as compared with other plant. There are many small country houses where owners would be prepared to wire a few of the principal rooms, and use, say, 200 units per annum at such a price, for even at 2s. 6d. per unit this would only amount to £25 per annum, which sum would often be gladly paid for the advantages gained. A strong feature of such a battery is that it requires no attention when not in use, and in this respect it is at an advantage as compared with accumulators.

The simplest method of working such a battery is to turn on the flow of electrolyte when the light is required, and the flow would be turned off on retiring at night. This would still permit the use of an occasional light during the night owing to the quantity of electrolyte in the cells, and it is stated that two or three 10 c.p. lamps could be supplied for the whole night by the battery here considered. It would seem, however, that some arrangement for the automatic regulation of the flow of electrolyte would be preferable in many cases, as the cost in practice must depend largely on the way in which the battery is used.

With regard to labour, it may be mentioned that the zincs weigh 1 lb., and if we take 3 lb. (a high figure to allow for waste and unused zinc) per unit, then a single cell will give ⅓ unit and a battery of 17 cells will give 5⅔ units before the zincs need be changed. If a house is using 1 to 2 units per day this means that the zincs are changed once or twice a week. As the operation is very simple it takes very little time.

From the point of view of labour the electrolyte is more important than the zinc. With a constant output the amount of electrolyte per unit will be, say, 7¾ galls. If, however, a battery such as we have assumed is allowed to flow steadily at a rate of ½ litre per cell, then a

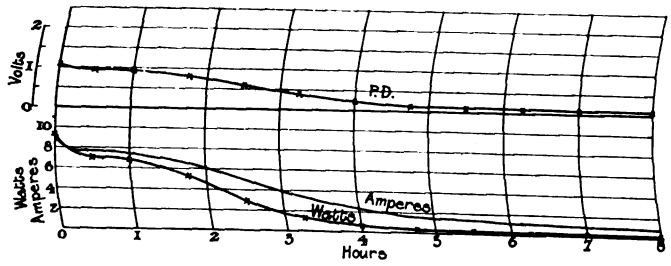

Fig. 7.—Discharge Curves of 3-pint Bichromate Cell, on same Circuit as in Fig. 6.
Solution "L."

5-hour run would require 9½ galls. This emphasises the desirability of automatic regulation of the flow. If hand regulation is adopted and not properly applied the amount of solution required might thus be as much as 15 galls. per day in the winter, or say, 10 galls. per day if the electrolyte is used twice and "refreshed" by adding new electrolyte to it. On the other hand, with automatic regulation this quantity once or twice a week for 1 to 2 units per week would be enough. With proper arrangements the handling of these quantities would take very little time. These figures emphasise the fact that the cost of running depends largely on the method of running.

As far as can be judged the cost of repairs should be very small, or negligible, and equally the interest on capital is scarcely worth considering. It follows, therefore, that electrical energy can be generated at about 2s. per unit under favourable conditions, and this cost will vary according to the carefulness of the regulation.

PHYSICAL SOCIETY.

At the meeting held on April 28th at the Imperial College of Science, Prof. H. L. Callendar, F.R.S., President, in the Chair, a

"High-tension Electrostatic Wattmeter"

was described by Prof. E. WILSON.

When using the Electrometer as a wattmeter it is necessary (in order to secure accuracy) that the voltage impressed upon the quadrants shall not be less than a certain minimum depending upon the voltage to be impressed upon the moving system. When the latter voltage is of the order 10,000, the quadrants require a voltage larger than can economically be provided by a shunt. One is led, therefore, to consider intensifying devices.

The "series" or "current" transformer, whose secondary winding is closed on a non-inductive resistance, can be used to give fairly good results, but it is not accurate at all frequencies and is dependent upon wave form.

The author's quadrature transformer is a very simple piece of apparatus which can be relied upon to give for electrostatic wattmeters an electromotive force that is strictly the differential of the current in the primary winding. When so used it is necessary, for accuracy, at all frequencies and on all wave forms, that the integral of the mains voltage shall be impressed upon the moving system, although for sine curves only the differential need be impressed instead of the integral.

The best device to impress on the quadrants a suitable voltage in phase with the currents is a generator with an air-cored magnetic circuit as described in the Paper. The mains current is passed through the field coil of the generator and produces a magnetic field proportional to the current; the armature is driven at known speed in this field, and is provided with a commutator and brushes. The brushes when set accurately have a voltage between them proportional to, and having the same wave form as, the mains current.

Another device depending upon the charging of condensers in parallel and the placing of them in series has also been used for multiplying a small voltage produced by the passage of the mains current through a low-resistance shunt.

Dr. SUMPNER pointed out that the reason why a fairly high voltage was needed on the quadrants together with a strong control on the needle when a very high voltage was applied to the latter was because of the action between the needle and the case; unless the case was quite symmetrical about the axis of the needle.

Dr RUSSELL inquired whether the author was troubled about brush discharges at the edges of the needle.

Mr. E. H. RAYNER pointed out that at low-power factors various errors in the apparatus would become large.
